<b>UTILITY PATENT APPLICATION TRANSMITTAL</b>  (Only for new nonprovisional applications under 37 CFR 1.53(b))	Attorney Docket No.	NPP023US
	First Inventor	KIA SILVERBROOK
	Title	INTERACTIVE PRINTER
	Express Mail Label No.	EK126698689US

<b>APPLICATION ELEMENTS</b> See MPEP chapter 600 concerning utility patent application contents.	<b>ADDRESS TO:</b> Assistant Commissioner for Patents Box Patent Application Washington, DC 20231	
1. <input checked="" type="checkbox"/> Fee Transmittal Form (e.g., PTO/SB/17) (Submit an original and a duplicate for fee processing)	7. <input type="checkbox"/> CD-ROM or CD-R in duplicate, large table or Computer Program (Appendix)	
2. <input checked="" type="checkbox"/> Applicant claims small entity status. See 37 CFR 1.27.	8. Nucleotide and/or Amino Acid Sequence Submission (if applicable, all necessary)	
3. <input checked="" type="checkbox"/> Specification [Total Pages 97] (preferred arrangement set forth below) - Descriptive title of the invention - Cross Reference to Related Applications - Statement Regarding Fed sponsored R & D - Reference to sequence listing, a table, or a computer program listing appendix - Background of the Invention - Brief Summary of the Invention - Brief Description of the Drawings (if filed) - Detailed Description - Claim(s) - Abstract of the Disclosure	a. <input type="checkbox"/> Computer Readable Form (CRF) b. Specification Sequence Listing on: i. <input type="checkbox"/> CD-ROM or CD-R (2 copies); or ii. <input type="checkbox"/> paper c. <input type="checkbox"/> Statements verifying identity of above copies	
4. <input checked="" type="checkbox"/> Drawing(s) (35 U.S.C. 113) [Total Sheets 61]	<b>ACCOMPANYING APPLICATION PARTS</b>	
5. Oath or Declaration [Total Pages 4] a. <input checked="" type="checkbox"/> Newly executed (original or copy) b. <input type="checkbox"/> Copy from a prior application (37 CFR 1.63 (d)) (for continuation/divisional with Box 17 completed) i. <input type="checkbox"/> DELETION OF INVENTOR(S) Signed statement attached deleting inventor(s) named in the prior application, see 37 CFR 1.63(d)(2) and 1.33(b)	9. <input checked="" type="checkbox"/> Assignment Papers (cover sheet & document(s))	
6. <input type="checkbox"/> Application Data Sheet. See 37 CFR 1.76	10. <input type="checkbox"/> 37 CFR 3.73(b) Statement (when there is an assignee)	<input type="checkbox"/> Power of Attorney
	11. <input type="checkbox"/> English Translation Document (if applicable)	
	12. <input type="checkbox"/> Information Disclosure Statement (IDS)/PTO-1449	<input type="checkbox"/> Copies of IDS Citations
	13. <input type="checkbox"/> Preliminary Amendment	
	14. <input type="checkbox"/> Return Receipt Postcard (MPEP 503) (Should be specifically itemized)	
	15. <input type="checkbox"/> Certified Copy of Priority Document(s) (if foreign priority is claimed)	
	16. <input type="checkbox"/> Other: .....	

17. If a CONTINUING APPLICATION, check appropriate box, and supply the requisite information below and in a preliminary amendment, or in an Application Data Sheet under 37 CFR 1.76:

☐ Continuation ☐ Divisional ☒ Continuation-in-part (CIP) of prior application No. 09,575,155

Prior application information Examiner Group I Art Unit 2853

For CONTINUATION OR DIVISIONAL APPS only: The entire disclosure of the prior application, from which an oath or declaration is supplied under Box 5b, is considered a part of the disclosure of the accompanying continuation or divisional application and is hereby incorporated by reference. The incorporation can only be relied upon when a portion has been inadvertently omitted from the submitted application parts.

Submitted herewith Utility Patent Application Transmittal and enclosures for an invention entitled "INTERACTIVE PRINTER".

Express Mail Label: EK126698689US

**THIS APPLICATION IS A CONTINUATION-IN-PART OF  
USSN 09/575155 FILED 23 MAY 2000**

**INTERACTIVE PRINTER**

**FIELD OF INVENTION**

- 5 The present invention relates to a printer for printing an interface onto a surface to produce an interface surface.

The invention has been developed primarily to produce interface surfaces which allow users to interact with networked information and to obtain interactive printed matter on demand via high-speed networked color printers. Although the invention will largely be  
10 described herein with reference to this use, it will be appreciated that the invention is not limited to use in this field.

**CO-PENDING APPLICATIONS**

- Various methods, systems and apparatus relating to the present invention are disclosed in the following co-pending applications filed by the applicant or assignee of  
15 the present invention simultaneously with the present invention:

NPA060US, NPA061US, NPA081US, NPA082US, NPP010US, NPP013US,  
NPP015US, NPP020US, NPP021US, NPP022US, NPP023US, NPS014US,  
NPS015US, NPS017US, NPS018US, NPS022US, NPS027US, NPS028US,  
NPT008US, BIN01US, BIN02US, BIN03US, BIN04US

20

The disclosures of these co-pending applications are incorporated herein by cross-reference. Each application is temporarily identified by its docket number. This will be replaced by the corresponding USSN when available.

- Various methods, systems and apparatus relating to the present invention are  
25 disclosed in the following co-pending applications filed by the applicant or assignee of the present invention on 20 October 2000:

NPA011US, NPA031US, NPA040US, NPA046US, NPA053US, NPA059US,  
NPA064US, NPB006US, NPS004US, NPS008US, NPS013US, NPS024US,  
UP01US, UP02US, UP03US, UP04US, UP05US

NPP023US

The disclosures of these co-pending applications are incorporated herein by cross-reference. Each application is temporarily identified by its docket number. This will be replaced by the corresponding USSN when available.

- 5           Various methods, systems and apparatus relating to the present invention are disclosed in the following co-pending applications filed by the applicant or assignee of the present invention on 15 September 2000:

NPA024US, NPA025US, NPA047US, NPA049US

- 10   The disclosures of these co-pending applications are incorporated herein by cross-reference. Each application is temporarily identified by its docket number. This will be replaced by the corresponding USSN when available.

- Various methods, systems and apparatus relating to the present invention are disclosed in the following co-pending applications filed by the applicant or assignee of  
15   the present invention on 30 June 2000:

NPA014US, NPA015US, NPA022US, NPA026US, NPA038US, NPA041US,  
NPA050US, NPA051US, NPA052US, NPA063US, NPA065US, NPA067US,  
NPA068US, NPA069US, NPA071US, NPA072US, NPB003US, NPB004US,  
NPB005US, NPP019US, PEC04US, PEC05US, PEC06US, PEC07US

- 20   The disclosures of these co-pending applications are incorporated herein by cross-reference. Each application is temporarily identified by its docket number. This will be replaced by the corresponding USSN when available.

- Various methods, systems and apparatus relating to the present invention are  
25   disclosed in the following co-pending applications filed by the applicant or assignee of the present invention on 23 May 2000:

- 30   NPA001US, NPA002US, NPA004US, NPA005US, NPA006US, NPA007US,  
NPA008US, NPA009US, NPA010US, NPA012US, NPA016US, NPA017US,  
NPA018US, NPA019US, NPA020US, NPA021US, NPA030US, NPA035US,  
NPA048US, NPA075US, NPB001US, NPB002US, NPK002US, NPK003US,

## BACKGROUND

Presently, a user of a computer system typically interacts with the system using a monitor for displaying information and a keyboard and/or mouse for inputting information. Whilst such an interface is powerful, it is relatively bulky and non-portable. Information  
5 printed on paper can be easier to read and more portable than information displayed on a computer monitor. However, unlike a keyboard or mouse, a pen on paper generally lacks the ability to interact with computer software.

## SUMMARY OF INVENTION

According to a first aspect of the invention, there is provided a printer for printing a  
10 second interface onto a second surface, in response to first indicating data received from a sensing device, the first indicating data being sensed by the sensing device from first coded data, a first interface disposed on a first surface including the first coded data, the printer including:

- (a) an input module configured to:
  - 15 (i) receive, from the sensing device, the first indicating data, the first indicating data being at least partially indicative of response data;
  - (ii) generate second indicating data based on the first indicating data, the second indicating data being at least partially indicative of the response data;
  - 20 (iii) send the second indicating data to a computer system; and
- (b) a printing module, including a printing mechanism, configured to:
  - (i) receive the response data from the computer system;
  - (ii) generate the second interface based at least partially on the response data; and
  - 25 (iii) print the second interface onto the second surface using the printing mechanism.

Preferably, the second interface includes second coded data, wherein the printing module includes a coded data generator configured to generate the second coded data based on at

least part of the response data. More preferably, the response data includes second region identity data indicative of at least one identity, the identity being associated with a region of the second interface, the coded data generator being configured to generate the second coded data based on the second region identity data, the second coded data being indicative of the identity.

In a preferred embodiment, the second interface includes visible information in addition to the second coded data, the visible information being based at least partially on the response data.

Preferably, the second coded data is also indicative of at least one reference point of the region. More preferably, the at least one reference point is determined on the basis of a coded data layout.

Preferably, the printing module is configured to receive the coded data layout from the computer system.

In one embodiment, the printer further includes storage means for storing a plurality of the coded data layouts, the printing module being configured to:

receive, from the computer system, layout selection information indicative of one of the coded data layouts; and

use the layout selection information to select one of the stored coded layouts for use in determining the at least one reference point.

Preferably, the first indicating data includes location data sensed by the sensing device from the first coded data.

In one preferred form, the first indicating data includes first region identity data sensed by the sensing device from the first coded data, the first region identity data being indicative of an identity associated with a region of the first interface, the region being at least partially indicative of the response data.

In another preferred form, the first indicating data includes location data sensed by the sensing device from the first coded data, the location data being indicative of a location within the region, the location within the region being at least partially indicative of the response data.

Preferably, the second coded data includes at least one tag, each tag being indicative of the identity of the region.

In a second aspect, the present invention provides a system including:

a printer according to the first aspect; and

- 5 a sensing device for sensing the first indicating data and transmitting it to the printer.

Preferably, the sensing device includes a radio transmitter for transmitting the indicating data to the printer, and the printer includes a radio receiver for receiving the indicating data.

- 10 In a preferred form, the sensing device includes an optical sensor for sensing the first coded data.

In a third aspect, the present invention provides a system including:

a printer according to the first aspect of the invention;

a first interface surface disposed on a first surface, the first interface surface including first coded data to be sensed by a sensing device, thereby to generate first indicating data

- 15 for transmission from the sensing device to the printer.

In a fourth aspect, the present invention provides an interface surface produced by a printer according to the first aspect.

Further objects and advantages of the invention will be apparent from the detailed description that follows.

## BRIEF DESCRIPTION OF DRAWINGS

Preferred and other embodiments of the invention will now be described, by way of non-limiting example only, with reference to the accompanying drawings, in which:

Figure 1 is a schematic of a the relationship between a sample printed netpage and its  
5 online page description;

Figure 2 is a schematic view of a interaction between a netpage pen, a netpage printer, a netpage page server, and a netpage application server;

Figure 3 illustrates a collection of netpage servers and printers interconnected via a network;

10 Figure 4 is a schematic view of a high-level structure of a printed netpage and its online page description;

Figure 5a is a plan view showing a structure of a netpage tag;

Figure 5b is a plan view showing a relationship between a set of the tags shown in Figure 5a and a field of view of a netpage sensing device in the form of a netpage pen;

15 Figure 6a is a plan view showing an alternative structure of a netpage tag;

Figure 6b is a plan view showing a relationship between a set of the tags shown in Figure 6a and a field of view of a netpage sensing device in the form of a netpage pen;

Figure 6c is a plan view showing an arrangement of nine of the tags shown in Figure 6a where targets are shared between adjacent tags;

20 Figure 6d is a plan view showing the interleaving and rotation of the symbols of the four codewords of the tag shown in Figure 6a;

Figure 7 is a flowchart of a tag image processing and decoding algorithm;

Figure 8 is a perspective view of a netpage pen and its associated tag-sensing field-of-view cone;

25 Figure 9 is a perspective exploded view of the netpage pen shown in Figure 8;

Figure 10 is a schematic block diagram of a pen controller for the netpage pen shown in Figures 8 and 9;

Figure 11 is a perspective view of a wall-mounted netpage printer;

Figure 12 is a section through the length of the netpage printer of Figure 11;

Figure 12a is an enlarged portion of Figure 12 showing a section of the duplexed print engines and glue wheel assembly;

Figure 68 is a section through the top part of the printer.

## DETAILED DESCRIPTION OF PREFERRED AND OTHER EMBODIMENTS

Note: Memjet™ is a trade mark of Silverbrook Research Pty Ltd, Australia.

- In the preferred embodiment, the invention is configured to work with the netpage networked computer system, a detailed overview of which follows. It will be appreciated
- 5 that not every implementation will necessarily embody all or even most of the specific details and extensions discussed below in relation to the basic system. However, the system is described in its most complete form to reduce the need for external reference when attempting to understand the context in which the preferred embodiments and aspects of the present invention operate.
- 10 In brief summary, the preferred form of the netpage system employs a computer interface in the form of a mapped surface, that is, a physical surface which contains references to a map of the surface maintained in a computer system. The map references can be queried by an appropriate sensing device. Depending upon the specific implementation, the map references may be encoded visibly or invisibly, and defined in such a way that a local
- 15 query on the mapped surface yields an unambiguous map reference both within the map and among different maps. The computer system can contain information about features on the mapped surface, and such information can be retrieved based on map references supplied by a sensing device used with the mapped surface. The information thus retrieved can take the form of actions which are initiated by the computer system on
- 20 behalf of the operator in response to the operator's interaction with the surface features.
- In its preferred form, the netpage system relies on the production of, and human interaction with, netpages. These are pages of text, graphics and images printed on ordinary paper, but which work like interactive web pages. Information is encoded on each page using ink which is substantially invisible to the unaided human eye. The ink,
- 25 however, and thereby the coded data, can be sensed by an optically imaging pen and transmitted to the netpage system. Substrates other than paper may be used. The encoded information in the preferred embodiment is an infrared absorptive ink and so an infrared sensitive optical sensor may be used. If desired other wavelengths may be used or sensing techniques other than optical sensing; one alternative is to use magnetic inks and
- 30 sensors.

In the preferred form, active buttons and hyperlinks on each page can be clicked with the pen to request information from the network or to signal preferences to a network server. In one embodiment, text written by hand on a netpage is automatically recognized and converted to computer text in the netpage system, allowing forms to be filled in. In other  
5   embodiments, signatures recorded on a netpage are automatically verified, allowing e-commerce transactions to be securely authorized.

As illustrated in Figure 1, a printed netpage 1 can represent a interactive form which can be filled in by the user both physically, on the printed page, and “electronically”, via communication between the pen and the netpage system. The example shows a  
10   “Request” form containing name and address fields and a submit button. The netpage consists of graphic data 2 printed using visible ink, and coded data 3 printed as a collection of tags 4 using invisible ink. The corresponding page description 5, stored on the netpage network, describes the individual elements of the netpage. In particular it describes the type and spatial extent (zone) of each interactive element (i.e. text field or  
15   button in the example), to allow the netpage system to correctly interpret input via the netpage. The submit button 6, for example, has a zone 7 which corresponds to the spatial extent of the corresponding graphic 8.

As illustrated in Figure 2, the netpage pen 101, a preferred form of which is shown in Figures 8 and 9 and described in more detail below, works in conjunction with a netpage  
20   printer 601, an Internet-connected printing appliance for home, office or mobile use. The pen is wireless and communicates securely with the netpage printer via a short-range radio link 9. If desired the pen may be connected to the system utilizing wires or an infrared transmitter, although both alternatives limit usability.

The netpage printer 601, a preferred form of which is shown in Figures 11 to 13 and  
25   described in more detail below, is able to deliver, periodically or on demand, personalized newspapers, magazines, catalogs, brochures and other publications, all printed at high quality as interactive netpages. Unlike a personal computer, the netpage printer is an appliance which can be, for example, wall-mounted adjacent to an area where the morning news is first consumed, such as in a user’s kitchen, near a breakfast  
30   table, or near the household’s point of departure for the day. It also comes in tabletop, desktop, portable and miniature versions.

Netpages printed at their point of consumption combine the ease-of-use of paper with the timeliness and interactivity of an interactive medium.

As shown in Figure 2, the netpage pen 101 interacts with the coded data on a printed netpage 1 and communicates, via a short-range radio link 9, the interaction to a netpage printer. The printer 601 sends the interaction to the relevant netpage page server 10 for interpretation. In appropriate circumstances, the page server sends a corresponding message to application computer software running on a netpage application server 13. The application server may in turn send a response which is printed on the originating printer.

- 10 The netpage system is made considerably more convenient in the preferred embodiment by being used in conjunction with high-speed microelectromechanical system (MEMS) based inkjet (Memjet™) printers. In the preferred form of this technology, relatively high-speed and high-quality printing is made more affordable to consumers. In its preferred form, a netpage publication has the physical characteristics of a traditional  
15 newsmagazine, such as a set of letter-size glossy pages printed in full color on both sides, bound together for easy navigation and comfortable handling.

- The netpage printer exploits the growing availability of broadband Internet access. Cable service is available to 95% of households in the United States, and cable modem service offering broadband Internet access is already available to 20% of these. The netpage  
20 printer can also operate with slower connections, but either with longer delivery times or lower image quality or both. Indeed, the netpage system can be enabled using existing consumer inkjet and laser printers, although the system will operate more slowly and will therefore be less acceptable from a consumer's point of view. In other embodiments, the netpage system is hosted on a private intranet. In still other embodiments, the netpage  
25 system is hosted on a single computer or computer-enabled device, such as a printer.

- Netpage publication servers 14 on the netpage network are configured to deliver print-quality publications to netpage printers. Periodical publications are delivered automatically to subscribing netpage printers via pointcasting and multicasting Internet protocols. Personalized publications are filtered and formatted according to individual  
30 user profiles.

A netpage printer can be configured to support any number of pens, and a pen can work with any number of netpage printers. In the preferred implementation, each netpage pen has a unique identifier. A household may have a collection of colored netpage pens, one assigned to each member of the family. This allows each user to maintain a distinct  
5 profile with respect to a netpage publication server or application server, assuming that the assigned pen is only used by the respective family member. However, as explained below, other means may be used to identify a user.

A netpage pen can also be registered with a netpage registration server 11 and linked to one or more payment card accounts. This allows e-commerce payments to be securely  
10 authorized using the netpage pen. The netpage registration server compares the signature captured by the netpage pen with a previously registered signature, allowing it to authenticate the user's identity to an e-commerce server. Other biometrics can also be used to verify identity. A version of the netpage pen includes fingerprint scanning, verified in a similar way by the netpage registration server.

15 Although a netpage printer may deliver periodicals such as the morning newspaper without user intervention, it can be configured never to deliver unsolicited junk mail. In its preferred form, it only delivers periodicals from subscribed or otherwise authorized sources. In this respect, the netpage printer is unlike a fax machine or e-mail account which is visible to any junk mailer who knows the telephone number or email address.  
20 Alternatively the entire system may be made visible to outside users or each user may be provided with the ability to expose their printer(s) to outside users. This may be by way of selecting outside users allowed too send junk mail.

## 1 NETPAGE SYSTEM ARCHITECTURE

Each object model in the system is described using a Unified Modeling Language  
25 (UML) class diagram. A class diagram consists of a set of object classes connected by relationships, and two kinds of relationships are of interest here: associations and generalizations. An association represents some kind of relationship between objects, i.e. between instances of classes. A generalization relates actual classes, and can be understood in the following way: if a class is thought of as the set of all objects of that  
30 class, and class A is a generalization of class B, then B is simply a subset of A.

Each class is drawn as a rectangle labeled with the name of the class. It contains a list of the attributes of the class, separated from the name by a horizontal line, and a list of the operations of the class, separated from the attribute list by a horizontal line. In the class diagrams which follow, however, operations are never modeled.

- 5 An association is drawn as a line joining two classes, optionally labeled at either end with the multiplicity of the association. The default multiplicity is one. An asterisk (\*) indicates a multiplicity of “many”, i.e. zero or more. Each association is optionally labeled with its name, and is also optionally labeled at either end with the role of the corresponding class. An open diamond indicates an aggregation association (“is-part-of”), and is drawn at the aggregator end of the association line.

A generalization relationship (“is-a”) is drawn as a solid line joining two classes, with an arrow (in the form of an open triangle) at the generalization end.

- When a class diagram is broken up into multiple diagrams, any class which is duplicated is shown with a dashed outline in all but the main diagram which defines it. It is shown with attributes only where it is defined.

## 1.1 NETPAGES

Netpages are the foundation on which a netpage network is built. They provide a paper-based user interface to published information and interactive services.

- A netpage consists of a printed page (or other surface region) invisibly tagged with references to an online description of the page. The tags may be printed on or into the surface of the page, may be in or on a sub-layer of the page or may be otherwise incorporated into the page. The online page description is maintained persistently by a netpage page server. The page description describes the visible layout and content of the page, including text, graphics and images. It also describes the input elements on the page, including buttons, hyperlinks, and input fields. The page descriptions of different netpages may share components, such as an image, although the netpages (and the associated page descriptions) are visibly different. The page description for each netpage may include references to these common components. A netpage allows markings made with a netpage pen on its surface to be simultaneously captured and processed by the netpage system.

Multiple netpages can share the same page description. However, to allow input through otherwise identical pages to be distinguished, each netpage is assigned a unique page identifier. This page ID has sufficient precision to distinguish between all netpages envisaged to be used in the environment of use. If the environment is small then the precision need not be as great as where the environment is large.

Each reference to the page description is encoded in a printed tag. The tag identifies the unique page on which it appears, and thereby indirectly identifies the page description. In the preferred embodiments the tag also identifies its own position on the page. Characteristics of the tags are described in more detail below.

- 10 Tags are printed in infrared-absorptive ink on any substrate which is infrared-reflective, such as ordinary paper. Near-infrared wavelengths are invisible to the human eye but are easily sensed by a solid-state image sensor with an appropriate filter. A sensor sensitive to the relative wavelength or wavelengths may be used, in which case no filters are required. Other wavelengths may be used, with appropriate substrates and sensors.
- 15 A tag is sensed by an area image sensor in the netpage pen, decoded and the data encoded by the tag is transmitted to the netpage system, preferably via the nearest netpage printer. The pen is wireless and communicates with the netpage printer via a short-range radio link. Tags are sufficiently small and densely arranged that the pen can reliably image at least one tag even on a single click on the page. It is important that the
- 20 pen recognize the tag and extract the page ID and position on every interaction with the page, since the interaction is stateless. Tags are error-correctably encoded to make them partially tolerant to surface damage.

The netpage page server maintains a unique page instance for each printed netpage, allowing it to maintain a distinct set of user-supplied values for input fields in the page description for each printed netpage.

The relationship between the page description, the page instance, and the printed netpage is shown in Figure 4. In the preferred embodiment the page instance is associated with both the netpage printer which printed it and, if known, the netpage user who requested it. It is not essential to the working of the invention in its basic form that the page

30 instance be associated with either the netpage printer which printed the corresponding

physical page or the netpage user who requested it or for whom the page was printed.

## 1.2 NETPAGE TAGS

### 1.2.1 Tag Data Content

- In a preferred form, each tag identifies the region in which it appears, and the location of that tag within the region. A tag may also contain flags which relate to the region as a whole or to the tag. One or more flag bits may, for example, signal a tag sensing device to provide feedback indicative of a function associated with the immediate area of the tag, without the sensing device having to refer to a description of the region. A netpage pen may, for example, illuminate an “active area” LED when in the zone of a hyperlink.
- As will be more clearly explained below, in a preferred embodiment, each tag contains an easily recognized invariant structure which aids initial detection, and which assists in minimizing the effect of any warp induced by the surface or by the sensing process. The tags preferably tile the entire page, and are sufficiently small and densely arranged that the pen can reliably image at least one tag even on a single click on the page. It is important that the pen recognize the page ID and position on every interaction with the page, since the interaction is stateless.

- In a preferred embodiment, the region to which a tag refers coincides with an entire page, and the region ID encoded in the tag is therefore synonymous with the page ID of the page on which the tag appears. In other embodiments, the region to which a tag refers can be an arbitrary subregion of a page or other surface. For example, it can coincide with the zone of an interactive element, in which case the region ID can directly identify the interactive element.

- Each tag typically contains 16 bits of tag ID, at least 90 bits of region ID, and a number of flag bits. Assuming a maximum tag density of 64 per square inch, a 16-bit tag ID supports a region size of up to 1024 square inches. Larger regions can be mapped continuously without increasing the tag ID precision simply by using abutting regions and maps. The distinction between a region ID and a tag ID is mostly one of convenience. For most purposes the concatenation of the two can be considered as a globally unique tag ID. Conversely, it may also be convenient to introduce structure into

the tag ID, for example to define the x and y coordinates of the tag. A 90-bit region ID allows  $2^{90}$  ( $\sim 10^{27}$  or a thousand trillion trillion) different regions to be uniquely identified. Tags may also contain type information, and a region may be tagged with a mixture of tag types. For example, a region may be tagged with one set of tags encoding x coordinates and another set, interleaved with the first, encoding y coordinates. It will be appreciated the region ID and tag ID precision may be more or less than just described depending on the environment in which the system will be used.

### 1.2.2 Tag Data Encoding

In one embodiment each tag contains 120 bits of information. The 120 bits of tag data are redundantly encoded using a (15, 5) Reed-Solomon code. This yields 360 encoded bits consisting of 6 codewords of 15 4-bit symbols each. The (15, 5) code allows up to 5 symbol errors to be corrected per codeword, i.e. it is tolerant of a symbol error rate of up to 33% per codeword.

Each 4-bit symbol is represented in a spatially coherent way in the tag, and the symbols of the six codewords are interleaved spatially within the tag. This ensures that a burst error (an error affecting multiple spatially adjacent bits) damages a minimum number of symbols overall and a minimum number of symbols in any one codeword, thus maximizing the likelihood that the burst error can be fully corrected.

Any suitable error-correcting code can be used in place of a (15, 5) Reed-Solomon code, for example a Reed-Solomon code with more or less redundancy, with the same or different symbol and codeword sizes; another block code; or a different kind of code, such as a convolutional code (see, for example, Stephen B. Wicker, Error Control Systems for Digital Communication and Storage, Prentice-Hall 1995, the contents of which are herein incorporated by cross-reference).

### 1.2.3 Physical Tag Structure

The physical representation of the tag, shown in Figure 5, includes fixed target structures 15, 16, 17 and variable data areas 18. The fixed target structures allow a sensing device such as the netpage pen to detect the tag and infer its three-dimensional orientation relative to the sensor. The data areas contain representations of the individual bits of the

encoded tag data.

To achieve proper tag reproduction, the tag is rendered at a resolution of 256×256 dots. When printed at 1600 dots per inch this yields a tag with a diameter of about 4 mm. At this resolution the tag is designed to be surrounded by a “quiet area” of radius 16 dots.

- 5 Since the quiet area is also contributed by adjacent tags, it only adds 16 dots to the effective diameter of the tag.

- The tag includes six target structures. A detection ring 15 allows the sensing device to initially detect the tag. The ring is easy to detect because it is rotationally invariant and because a simple correction of its aspect ratio removes most of the effects of perspective distortion. An orientation axis 16 allows the sensing device to determine the approximate planar orientation of the tag due to the yaw of the sensor. The orientation axis is skewed to yield a unique orientation. Four perspective targets 17 allow the sensing device to infer an accurate two-dimensional perspective transform of the tag and hence an accurate three-dimensional position and orientation of the tag relative to the sensor.

- 15 All target structures are redundantly large to improve their immunity to noise.

- The overall tag shape is circular. This supports, amongst other things, optimal tag packing on an irregular triangular grid, such as is required to tile an arbitrary non-planar surface. The tags may, however, be arranged at the apexes of any polygon having  $n$  apexes, where  $n$  ranges from 3 to infinity, as desired. In combination with the circular detection ring 15, this makes a circular arrangement of data bits within the tag optimal. As shown in Figure 48, to maximize its size, each data bit is represented by a radial wedge 510 in the form of an area bounded by two radial lines 512, a radially inner arc 514 and a radially outer arc 516. Each wedge 510 has a minimum dimension of 8 dots at 1600 dpi and is designed so that its base (i.e. its inner arc 514), is at least equal to this minimum dimension. The radial height of the wedge 510 is always equal to the minimum dimension. Each 4-bit data symbol is represented by an array 518 of 2×2 wedges 510, as best shown in Figure 48.

- The 15 4-bit data symbols of each of the six codewords are allocated to the four concentric symbol rings 18a to 18d, shown in Figure 5, in interleaved fashion as shown in Figures 49 to 51. Symbols of first to sixth codewords 520-525 are allocated alternately

in circular progression around the tag.

The interleaving is designed to maximize the average spatial distance between any two symbols of the same codeword. Other arrangements of the codewords or their data symbols may be utilized.

- 5 The physical layout of the tags or the shape and/or arrangement of data symbols within each tag are not essential to the working of the invention. It is merely necessary that each tag encode sufficient information for the intended use. The use of redundancy in the tag is preferred but, at its basic level, not truly essential to the working of the invention. As such other tag arrangements may be utilized. Examples of other tag structures are  
10 described in US Patents 5,625,412, 5,661,506, 5,477,012 and 5,852,434, and PCT application PCT/US98/20597, the contents of each of which are incorporated herein by reference.

- In order to support "single-click" interaction with a tagged region via a sensing device, the sensing device must be able to see at least one entire tag in its field of view no matter  
15 where in the region or at what orientation the sensing device is positioned. The required diameter of the field of view of the sensing device is therefore a function of the size and spacing of the tags.

Assuming a circular tag shape, the minimum diameter of the sensor field of view is obtained when the tags are tiled on an equilateral triangular grid, as shown in Figure 6.

#### 20 1.2.4 Tag Image Processing and Decoding

- The tag image processing and decoding of a tag of figure 5 performed by a sensing device such as the netpage pen is shown in Figure 7. While a captured image is being acquired from the image sensor, the dynamic range of the image is determined (at 20). The center of the range is then chosen as the binary threshold for the image 21. The  
25 image is then thresholded and segmented into connected pixel regions (i.e. shapes 23) (at 22). Shapes which are too small to represent tag target structures are discarded. The size and centroid of each shape is also computed.

Binary shape moments 25 are then computed (at 24) for each shape, and these provide the basis for subsequently locating target structures. Central shape moments are by their

nature invariant of position, and can be easily made invariant of scale, aspect ratio and rotation.

The ring target structure 15 is the first to be located (at 26). A ring has the advantage of being very well behaved when perspective-distorted. Matching proceeds by aspect-normalizing and rotation-normalizing each shape's moments. Once its second-order moments are normalized the ring is easy to recognize even if the perspective distortion was significant. The ring's original aspect and rotation 27 together provide a useful approximation of the perspective transform.

The axis target structure 16 is the next to be located (at 28). Matching proceeds by applying the ring's normalizations to each shape's moments, and rotation-normalizing the resulting moments. Once its second-order moments are normalized the axis target is easily recognized. Note that one third order moment is required to disambiguate the two possible orientations of the axis. The shape is deliberately skewed to one side to make this possible. Note also that it is only possible to rotation-normalize the axis target after it has had the ring's normalizations applied, since the perspective distortion can hide the axis target's axis. The axis target's original rotation provides a useful approximation of the tag's rotation due to pen yaw 29.

The four perspective target structures 17 are the last to be located (at 30). Good estimates of their positions are computed based on their known spatial relationships to the ring and axis targets, the aspect and rotation of the ring, and the rotation of the axis. Matching proceeds by applying the ring's normalizations to each shape's moments. Once their second-order moments are normalized the circular perspective targets are easy to recognize, and the target closest to each estimated position is taken as a match. The original centroids of the four perspective targets are then taken to be the perspective-distorted corners 31 of a square of known size in tag space, and an eight-degree-of-freedom perspective transform 33 is inferred (at 32) based on solving the well-understood equations relating the four tag-space and image-space point pairs (see Heckbert, P., Fundamentals of Texture Mapping and Image Warping, Masters Thesis, Dept. of EECS, U. of California at Berkeley, Technical Report No. UCB/CSD 89/516, June 1989, the contents of which are herein incorporated by cross-reference).

The inferred tag-space to image-space perspective transform is used to project (at 36)

each known data bit position in tag space into image space where the real-valued position is used to bilinearly interpolate (at 36) the four relevant adjacent pixels in the input image. The previously computed image threshold 21 is used to threshold the result to produce the final bit value 37.

- 5 Once all 360 data bits 37 have been obtained in this way, each of the six 60-bit Reed-Solomon codewords is decoded (at 38) to yield 20 decoded bits 39, or 120 decoded bits in total. Note that the codeword symbols are sampled in codeword order, so that codewords are implicitly de-interleaved during the sampling process.

As mentioned above, the physical tag structure or encoding system is not essential to the  
10 invention and other physical arrangements of each tag may be used. It will be understood that the process for recognizing and decoding the tag image to retrieve the data encoded depends on the physical structure of the tag and the system used for redundantly encoding the data.

The ring target 15 is only sought in a subarea of the image whose relationship to the  
15 image guarantees that the ring, if found, is part of a complete tag. If a complete tag is not found and successfully decoded, then no pen position is recorded for the current frame. Given adequate processing power and ideally a non-minimal field of view 193, an alternative strategy involves seeking another tag in the current image.

The obtained tag data indicates the identity of the region containing the tag and the  
20 position of the tag within the region. An accurate position 35 of the pen nib in the region, as well as the overall orientation 35 of the pen, is then inferred (at 34) from the perspective transform 33 observed on the tag and the known spatial relationship between the pen's physical axis and the pen's optical axis.

### 1.2.5 Alternative Tag Structures

- 25 The tag structure just described is designed to allow both regular tilings of planar surfaces and irregular tilings of non-planar surfaces. Regular tilings are not, in general, possible on non-planar surfaces. In the more usual case of planar surfaces where regular tilings of tags are possible, i.e. surfaces such as sheets of paper and the like, more efficient tag structures can be used which exploit the regular nature of the tiling.

An alternative tag structure more suited to a regular tiling is shown in Figure 6a. The alternative tag 4 is square and has four perspective targets 17. It is similar in structure to tags described by Bennett et al. in US Patent 5051746. The tag represents sixty 4-bit Reed-Solomon symbols 47, for a total of 240 bits. The tag represents each one bit as a dot 48, and each zero bit by the absence of the corresponding dot. The perspective targets are designed to be shared between adjacent tags, as shown in Figures 6b and 6c. Figure 6b shows a square tiling of 16 tags and the corresponding minimum field of view 193, which must span the diagonals of two tags. Figure 6c shows a square tiling of nine tags, containing all one bits for illustration purposes.

- 10 Using a (15, 7) Reed-Solomon code, 112 bits of tag data are redundantly encoded to produce 240 encoded bits. The four codewords are interleaved spatially within the tag to maximize resilience to burst errors. Assuming a 16-bit tag ID as before, this allows a region ID of up to 92 bits.

- 15 The data-bearing dots 48 of the tag are designed to not overlap their neighbors, so that groups of tags cannot produce structures which resemble targets. This also saves ink. The perspective targets therefore allow detection of the tag, so further targets are not required. Tag image processing proceeds as described in section 1.2.4 above, with the exception that steps 26 and 28 are omitted.

- 20 Although the tag may contain an orientation feature to allow disambiguation of the four possible orientations of the tag relative to the sensor, it is also possible to embed orientation data in the tag data. For example, the four codewords can be arranged so that each tag orientation contains one codeword placed at that orientation, as shown in Figure 6d, where each symbol is labelled with the number of its codeword (1-4) and the position of the symbol within the codeword (A-O). Tag decoding then consists of decoding one
- 25 codeword at each orientation. Each codeword can either contain a single bit indicating whether it is the first codeword, or two bits indicating which codeword it is. The latter approach has the advantage that if, say, the data content of only one codeword is required, then at most two codewords need to be decoded to obtain the desired data. This may be the case if the region ID is not expected to change within a stroke and is thus
- 30 only decoded at the start of a stroke. Within a stroke only the codeword containing the tag ID is then desired. Furthermore, since the rotation of the sensing device changes

slowly and predictably within a stroke, only one codeword typically needs to be decoded per frame.

It is possible to dispense with perspective targets altogether and instead rely on the data representation being self-registering. In this case each bit value (or multi-bit value) is typically represented by an explicit glyph, i.e. no bit value is represented by the absence of a glyph. This ensures that the data grid is well-populated, and thus allows the grid to be reliably identified and its perspective distortion detected and subsequently corrected during data sampling. To allow tag boundaries to be detected, each tag data must contain a marker pattern, and these must be redundantly encoded to allow reliable detection. The overhead of such marker patterns is similar to the overhead of explicit perspective targets. One such scheme uses dots positioned at various points relative to grid vertices to represent different glyphs and hence different multi-bit values (see Anoto Technology Description, Anoto April 2000).

### 1.2.6 Tag Map

Decoding a tag results in a region ID, a tag ID, and a tag-relative pen transform. Before the tag ID and the tag-relative pen location can be translated into an absolute location within the tagged region, the location of the tag within the region must be known. This is given by a tag map, a function which maps each tag ID in a tagged region to a corresponding location. The tag map class diagram is shown in Figure 22, as part of the netpage printer class diagram.

A tag map reflects the scheme used to tile the surface region with tags, and this can vary according to surface type. When multiple tagged regions share the same tiling scheme and the same tag numbering scheme, they can also share the same tag map.

The tag map for a region must be retrievable via the region ID. Thus, given a region ID, a tag ID and a pen transform, the tag map can be retrieved, the tag ID can be translated into an absolute tag location within the region, and the tag-relative pen location can be added to the tag location to yield an absolute pen location within the region.

### 1.2.7 Tagging Schemes

Two distinct surface coding schemes are of interest, both of which use the tag structure

described earlier in this section. The preferred coding scheme uses “location-indicating” tags as already discussed. An alternative coding scheme uses “object-indicating” tags.

A location-indicating tag contains a tag ID which, when translated through the tag map associated with the tagged region, yields a unique tag location within the region. The tag-  
5 relative location of the pen is added to this tag location to yield the location of the pen within the region. This in turn is used to determine the location of the pen relative to a user interface element in the page description associated with the region. Not only is the user interface element itself identified, but a location relative to the user interface element is identified. Location-indicating tags therefore trivially support the capture of  
10 an absolute pen path in the zone of a particular user interface element.

An object-indicating tag contains a tag ID which directly identifies a user interface element in the page description associated with the region. All the tags in the zone of the user interface element identify the user interface element, making them all identical and therefore indistinguishable. Object-indicating tags do not, therefore, support the capture  
15 of an absolute pen path. They do, however, support the capture of a relative pen path. So long as the position sampling frequency exceeds twice the encountered tag frequency, the displacement from one sampled pen position to the next within a stroke can be unambiguously determined.

With either tagging scheme, the tags function in cooperation with associated visual  
20 elements on the netpage as user interactive elements in that a user can interact with the printed page using an appropriate sensing device in order for tag data to be read by the sensing device and for an appropriate response to be generated in the netpage system.

### 1.3 DOCUMENT AND PAGE DESCRIPTIONS

A preferred embodiment of a document and page description class diagram is shown in  
25 Figures 25 and 26.

In the netpage system a document is described at three levels. At the most abstract level the document 836 has a hierarchical structure whose terminal elements 839 are associated with content objects 840 such as text objects, text style objects, image objects, etc. Once the document is printed on a printer with a particular page size and according  
30 to a particular user’s scale factor preference, the document is paginated and otherwise

formatted. Formatted terminal elements 835 will in some cases be associated with content objects which are different from those associated with their corresponding terminal elements, particularly where the content objects are style-related. Each printed instance of a document and page is also described separately, to allow input captured through a particular page instance 830 to be recorded separately from input captured through other instances of the same page description.

The presence of the most abstract document description on the page server allows a user to request a copy of a document without being forced to accept the source document's specific format. The user may be requesting a copy through a printer with a different page size, for example. Conversely, the presence of the formatted document description on the page server allows the page server to efficiently interpret user actions on a particular printed page.

A formatted document 834 consists of a set of formatted page descriptions 5, each of which consists of a set of formatted terminal elements 835. Each formatted element has a spatial extent or zone 58 on the page. This defines the active area of input elements such as hyperlinks and input fields.

A document instance 831 corresponds to a formatted document 834. It consists of a set of page instances 830, each of which corresponds to a page description 5 of the formatted document. Each page instance 830 describes a single unique printed netpage 1, and records the page ID 50 of the netpage. A page instance is not part of a document instance if it represents a copy of a page requested in isolation.

A page instance consists of a set of terminal element instances 832. An element instance only exists if it records instance-specific information. Thus, a hyperlink instance exists for a hyperlink element because it records a transaction ID 55 which is specific to the page instance, and a field instance exists for a field element because it records input specific to the page instance. An element instance does not exist, however, for static elements such as textflows.

A terminal element can be a static element 843, a hyperlink element 844, a field element 845 or a page server command element 846, as shown in Figure 27. A static element 843 can be a style element 847 with an associated style object 854, a textflow element 848

with an associated styled text object 855, an image element 849 with an associated image element 856, a graphic element 850 with an associated graphic object 857, a video clip element 851 with an associated video clip object 858, an audio clip element 852 with an associated audio clip object 859, or a script element 853 with an associated script object 860, as shown in Figure 28.

A page instance may have a background field 833 which is used to record any digital ink captured on the page which does not apply to a specific input element.

In the preferred form of the invention, a tag map 811 is associated with each page instance to allow tags on the page to be translated into locations on the page.

#### 10 1.4 THE NETPAGE NETWORK

In a preferred embodiment, a netpage network consists of a distributed set of netpage page servers 10, netpage registration servers 11, netpage ID servers 12, netpage application servers 13, netpage publication servers 14, and netpage printers 601 connected via a network 19 such as the Internet, as shown in Figure 3.

15 The netpage registration server 11 is a server which records relationships between users, pens, printers, applications and publications, and thereby authorizes various network activities. It authenticates users and acts as a signing proxy on behalf of authenticated users in application transactions. It also provides handwriting recognition services if desired. As described above, a netpage page server 10 maintains persistent information  
20 about page descriptions and page instances. The netpage network includes any number of page servers, each handling a subset of page instances. Since a page server also maintains user input values for each page instance, clients such as netpage printers send netpage input directly to the appropriate page server. The page server interprets any such input relative to the description of the corresponding page.

25 A netpage ID server 12 allocates document IDs 51 on demand, and provides load-balancing of page servers via its ID allocation scheme.

A netpage printer uses the Internet Distributed Name System (DNS), or similar, to resolve a netpage page ID 50 into the network address of the netpage page server handling the corresponding page instance.

A netpage application server 13 is a server which hosts interactive netpage applications. A netpage publication server 14 is an application server which publishes netpage documents to netpage printers. They are described in detail in Section 2.

Netpage servers can be hosted on a variety of network server platforms from 5 manufacturers such as IBM, Hewlett-Packard, and Sun. Multiple netpage servers can run concurrently on a single host, and a single server can be distributed over a number of hosts. Some or all of the functionality provided by netpage servers, and in particular the functionality provided by the ID server and the page server, can also be provided directly in a netpage appliance such as a netpage printer, in a computer workstation, or on a local 10 network.

### 1.5 THE NETPAGE PRINTER

The netpage printer 601 is an appliance which is registered with the netpage system and prints netpage documents on demand and via subscription. Each printer has a unique printer ID 62, and is connected to the netpage network via a network such as the Internet, 15 ideally via a broadband connection.

Apart from identity and security settings in non-volatile memory, the netpage printer need not contain any persistent storage. As far as a user is concerned, "the network is the computer". Netpages function interactively across space and time with the help of the distributed netpage page servers 10, independently of particular netpage printers.

20 The netpage printer receives subscribed netpage documents from netpage publication servers 14. Each document is distributed in two parts: the page layouts, and the actual text and image objects which populate the pages. Because of personalization, page layouts are typically specific to a particular subscriber and so are pointcast to the subscriber's printer via the appropriate page server. Text and image objects, on the other 25 hand, are typically shared with other subscribers, and so are multicast to all subscribers' printers and the appropriate page servers.

The netpage publication server optimizes the segmentation of document content into pointcasts and multicasts. After receiving the pointcast of a document's page layouts, the printer knows which multicasts, if any, to listen to.

Once the printer has received the complete page layouts and objects that define the document to be printed, it can print the document.

The printer rasterizes and prints odd and even pages simultaneously on both sides of the sheet. It contains duplexed print engine controllers 760 and print engines utilizing  
5 Memjet™ printheads 350 for this purpose.

The printing process consists of two decoupled stages: rasterization of page descriptions, and expansion and printing of page images. The raster image processor (RIP) consists of one or more standard DSPs 757 running in parallel. The duplexed print engine controllers consist of custom processors which expand, dither and print page images in  
10 real time, synchronized with the operation of the printheads in the print engines.

Printers not enabled for invisible IR printing have the option to print tags using IR-absorptive black ink, although this restricts tags to otherwise empty areas of the page. Although such pages have more limited functionality than invisible IR-printed pages, they are still classed as netpages.

15 A normal netpage printer prints netpages on sheets of paper. More specialized netpage printers may print onto more specialized surfaces, such as globes or sheets of plastics. Each printer supports at least one surface type, and supports at least one tag tiling scheme, and hence tag map, for each surface type. The tag map 811 which describes the tag tiling scheme actually used to print a document becomes associated with  
20 that document so that the document's tags can be correctly interpreted.

Figure 2 shows the netpage printer class diagram, reflecting printer-related information maintained by a registration server 11 on the netpage network.

A preferred embodiment of the netpage printer is described in greater detail in Section 6 below, with reference to Figures 11 to 16.

### 25 1.5.1 Memjet™ Printheads

The netpage system can operate using printers made with a wide range of digital printing technologies, including thermal inkjet, piezoelectric inkjet, laser electrophotographic, and others. However, for wide consumer acceptance, it is desirable that a netpage printer have the following characteristics:

- photographic quality color printing
- high quality text printing
- high reliability
- low printer cost
- 5 • low ink cost
- low paper cost
- simple operation
- nearly silent printing
- high printing speed
- 10 • simultaneous double sided printing
- compact form factor
- low power consumption

No currently commercially available printing technology has all of these characteristics.

- To enable production of printers with these characteristics, the present applicant has
- 15 invented a new print technology, referred to as Memjet™ technology. Memjet™ is a drop-on-demand inkjet technology that incorporates pagewidth printheads fabricated using microelectromechanical systems (MEMS) technology. Figure 17 shows a single printing element 300 of a Memjet™ printhead. The netpage wallprinter incorporates 168960 printing elements 300 to form a 1600 dpi pagewidth duplex printer. This printer
- 20 simultaneously prints cyan, magenta, yellow, black, and infrared inks as well as paper conditioner and ink fixative.

The printing element 300 is approximately 110 microns long by 32 microns wide. Arrays of these printing elements are formed on a silicon substrate 301 that incorporates CMOS logic, data transfer, timing, and drive circuits (not shown).

- 25 Major elements of the printing element 300 are the nozzle 302, the nozzle rim 303, the nozzle chamber 304, the fluidic seal 305, the ink channel rim 306, the lever arm 307, the active actuator beam pair 308, the passive actuator beam pair 309, the active actuator

anchor 310, the passive actuator anchor 311, and the ink inlet 312.

The active actuator beam pair 308 is mechanically joined to the passive actuator beam pair 309 at the join 319. Both beams pairs are anchored at their respective anchor points 310 and 311. The combination of elements 308, 309, 310, 311, and 319 form a  
5 cantilevered electrothermal bend actuator 320.

Figure 18 shows a small part of an array of printing elements 300, including a cross section 315 of a printing element 300. The cross section 315 is shown without ink, to clearly show the ink inlet 312 that passes through the silicon wafer 301.

Figures 19(a), 19(b) and 19(c) show the operating cycle of a Memjet™ printing element  
10 300.

Figure 19(a) shows the quiescent position of the ink meniscus 316 prior to printing an ink droplet. Ink is retained in the nozzle chamber by surface tension at the ink meniscus 316 and at the fluidic seal 305 formed between the nozzle chamber 304 and the ink channel rim 306.

15 While printing, the printhead CMOS circuitry distributes data from the print engine controller to the correct printing element, latches the data, and buffers the data to drive the electrodes 318 of the active actuator beam pair 308. This causes an electrical current to pass through the beam pair 308 for about one microsecond, resulting in Joule heating. The temperature increase resulting from Joule heating causes the beam pair 308 to  
20 expand. As the passive actuator beam pair 309 is not heated, it does not expand, resulting in a stress difference between the two beam pairs. This stress difference is partially resolved by the cantilevered end of the electrothermal bend actuator 320 bending towards the substrate 301. The lever arm 307 transmits this movement to the nozzle chamber 304. The nozzle chamber 304 moves about two microns to the position shown  
25 in Figure 19(b). This increases the ink pressure, forcing ink 321 out of the nozzle 302, and causing the ink meniscus 316 to bulge. The nozzle rim 303 prevents the ink meniscus 316 from spreading across the surface of the nozzle chamber 304.

As the temperature of the beam pairs 308 and 309 equalizes, the actuator 320 returns to its original position. This aids in the break-off of the ink droplet 317 from the ink 321 in  
30 the nozzle chamber, as shown in Figure 19(c). The nozzle chamber is refilled by the

action of the surface tension at the meniscus 316.

Figure 20 shows a segment of a printhead 350. In a netpage printer, the length of the printhead is the full width of the paper (typically 210 mm) in the direction 351. The segment shown is 0.4 mm long (about 0.2% of a complete printhead). When printing, the paper is moved past the fixed printhead in the direction 352. The printhead has 6 rows of interdigitated printing elements 300, printing the six colors or types of ink supplied by the ink inlets 312.

To protect the fragile surface of the printhead during operation, a nozzle guard wafer 330 is attached to the printhead substrate 301. For each nozzle 302 there is a corresponding nozzle guard hole 331 through which the ink droplets are fired. To prevent the nozzle guard holes 331 from becoming blocked by paper fibers or other debris, filtered air is pumped through the air inlets 332 and out of the nozzle guard holes during printing. To prevent ink 321 from drying, the nozzle guard is sealed while the printer is idle.

## 1.6 The Netpage Pen

The active sensing device of the netpage system is typically a pen 101, which, using its embedded controller 134, is able to capture and decode IR position tags from a page via an image sensor. The image sensor is a solid-state device provided with an appropriate filter to permit sensing at only near-infrared wavelengths. As described in more detail below, the system is able to sense when the nib is in contact with the surface, and the pen is able to sense tags at a sufficient rate to capture human handwriting (i.e. at 200 dpi or greater and 100 Hz or faster). Information captured by the pen is encrypted and wirelessly transmitted to the printer (or base station), the printer or base station interpreting the data with respect to the (known) page, or, in the preferred embodiment, transmitting the information to a netpage server for interpretation.

The preferred embodiment of the netpage pen operates both as a marking ink pen and as a non-marking stylus. The marking aspect, however, is not necessary for using the netpage system as a browsing system, such as when it is used as an Internet interface. Each netpage pen is registered with the netpage system and has a unique pen ID 61. Figure 23 shows the netpage pen class diagram, reflecting pen-related information maintained by a registration server 11 on the netpage network.

When either nib is in contact with a netpage, the pen determines its position and orientation relative to the page. The nib is attached to a force sensor, and the force on the nib is interpreted relative to a threshold to indicate whether the pen is “up” or “down”. This allows a interactive element on the page to be ‘clicked’ by pressing with the pen nib, in order to request, say, information from a network. Furthermore, the force is captured as a continuous value to allow, say, the full dynamics of a signature to be verified. The nib may be movable when subject to a specified force which is greater than that normally applied when writing. To “click” the user applies a force sufficient to move the nib. This may provide more desirable feedback to the user compared to that provided by a non-moving nib.

The pen determines the position and orientation of its nib on the netpage by imaging, in the infrared spectrum, an area 193 of the page in the vicinity of the nib. It decodes the nearest tag and computes the position of the nib relative to the tag from the observed perspective distortion on the imaged tag and the known geometry of the pen optics. Although the position resolution of the tag may be low, because the tag density on the page is inversely proportional to the tag size, the adjusted position resolution is quite high, exceeding the minimum resolution required for accurate handwriting recognition.

Pen actions relative to a netpage are captured as a series of strokes. A stroke consists of a sequence of time-stamped pen positions on the page, initiated by a pen-down event and completed by the subsequent pen-up event. A stroke is also tagged with the page ID 50 of the netpage whenever the page ID changes, which, under normal circumstances, is at the commencement of the stroke.

Each netpage pen has a current selection 826 associated with it, allowing the user to perform copy and paste operations etc. The selection is time-stamped to allow the system to discard it after a defined time period. The current selection describes a region of a page instance. It consists of the most recent digital ink stroke captured through the pen relative to the background area of the page. It is interpreted in an application-specific manner once it is submitted to an application via a selection hyperlink activation.

Each pen has a current nib 824. This is the nib last notified by the pen to the system. In the case of the default netpage pen described above, either the marking ink nib or the non-marking stylus nib is current. Each pen also has a current nib style 825. This is the

nib style last associated with the pen by an application, e.g. in response to the user selecting a color from a palette. The default nib style is the nib style associated with the current nib. Strokes captured through a pen are tagged with the current nib style. When the strokes are subsequently reproduced, they are reproduced in the nib style with which they are tagged.

Whenever the pen is within range of a printer with which it can communicate, the pen slowly flashes its "online" LED. When the pen fails to decode a stroke relative to the page, it momentarily activates its "error" LED. When the pen succeeds in decoding a stroke relative to the page, it momentarily activates its "ok" LED.

10 A sequence of captured strokes is referred to as digital ink. Digital ink forms the basis for the digital exchange of drawings and handwriting, for online recognition of handwriting, and for online verification of signatures.

The pen is wireless and transmits digital ink to the netpage printer via a short-range radio link. The transmitted digital ink is encrypted for privacy and security and packetized for efficient transmission, but is always flushed on a pen-up event to ensure timely handling in the printer.

When the pen is out of range of a printer it buffers digital ink in internal memory, which has a capacity of over ten minutes of continuous handwriting. When the pen is once again within range of a printer, it transfers any buffered digital ink. The buffer may provide more or less buffer capacity.

A pen can be registered with any number of printers, but because all state data resides in netpages both on paper and on the network, it is largely immaterial which printer a pen is communicating with at any particular time.

A preferred embodiment of the pen is described in greater detail in Section 6 below, with reference to Figures 8 to 10.

## 1.7 NETPAGE INTERACTION

The netpage printer 601 receives data relating to a stroke from the pen 101 when the pen is used to interact with a netpage 1. The coded data 3 of the tags 4 is read by the pen when it is used to execute a movement, such as a stroke. The data allows the identity of

the particular page and associated interactive element to be determined and an indication of the relative positioning of the pen relative to the page to be obtained. The indicating data is transmitted to the printer, where it resolves, via the DNS, the page ID 50 of the stroke into the network address of the netpage page server 10 which maintains the corresponding page instance 830. It then transmits the stroke to the page server. If the page was recently identified in an earlier stroke, then the printer may already have the address of the relevant page server in its cache. Each netpage consists of a compact page layout maintained persistently by a netpage page server (see below). The page layout refers to objects such as images, fonts and pieces of text, typically stored elsewhere on the netpage network.

When the page server receives the stroke from the pen, it retrieves the page description to which the stroke applies, and determines which element of the page description the stroke intersects. It is then able to interpret the stroke in the context of the type of the relevant element.

15 A “click” is typically a stroke where the distance and time between the pen down position and the subsequent pen up position are both less than some small maximum. An object which is activated by a click typically requires a click to be activated, and accordingly, a longer stroke is ignored. The failure of a pen action, such as a “sloppy” click, to register is indicated by the lack of response from the pen’s “ok” LED. However, where a netpage includes a button a “click” can be registered when both the pen down and pen up positions are both within the area of the button.

There are two kinds of input elements in a netpage page description: hyperlinks and form fields. Input through a form field can also trigger the activation of an associated hyperlink.

### 25 1.7.1 Hyperlinks

A hyperlink is a means of sending a message to a remote application, and typically elicits a printed response in the netpage system.

A hyperlink element 844 identifies the application 71 which handles activation of the hyperlink, a link ID 54 which identifies the hyperlink to the application, an “alias required” flag which asks the system to include the user’s application alias ID 65 in the

hyperlink activation, and a description which is used when the hyperlink is recorded as a favorite or appears in the user's history. The hyperlink element class diagram is shown in Figure 29.

- When a hyperlink is activated, the page server sends a request to an application  
5 somewhere on the network. The application is identified by an application ID 64, and the application ID is resolved in the normal way via the DNS. There are three types of hyperlinks: general hyperlinks 863, form hyperlinks 865, and selection hyperlinks 864, as shown in Figure 30. A general hyperlink can implement a request for a linked document, or may simply signal a preference to a server. A form hyperlink submits the  
10 corresponding form to the application. A selection hyperlink submits the current selection to the application. If the current selection contains a single-word piece of text, for example, the application may return a single-page document giving the word's meaning within the context in which it appears, or a translation into a different language. Each hyperlink type is characterized by what information is submitted to the application.
- 15 The corresponding hyperlink instance 862 records a transaction ID 55 which can be specific to the page instance on which the hyperlink instance appears. The transaction ID can identify user-specific data to the application, for example a "shopping cart" of pending purchases maintained by a purchasing application on behalf of the user.

- The system includes the pen's current selection 826 in a selection hyperlink activation.
- 20 The system includes the content of the associated form instance 868 in a form hyperlink activation, although if the hyperlink has its "submit delta" attribute set, only input since the last form submission is included. The system includes an effective return path in all hyperlink activations.

- A hyperlinked group 866 is a group element 838 which has an associated hyperlink, as  
25 shown in Figure 31. When input occurs through any field element in the group, the hyperlink 844 associated with the group is activated. A hyperlinked group can be used to associate hyperlink behavior with a field such as a checkbox. It can also be used, in conjunction with the "submit delta" attribute of a form hyperlink, to provide continuous input to an application. It can therefore be used to support a "blackboard" interaction  
30 model, i.e. where input is captured and therefore shared as soon as it occurs.

### 1.7.2 Forms

A form defines a collection of related input fields used to capture a related set of inputs through one or more printed netpages. A form allows a user to submit one or more parameters to an application software program running on a server.

- 5 A form 867 is a group element 838 in the document hierarchy. It ultimately contains a set of terminal field elements 839. A form instance 868 represents a printed instance of a form. It includes a set of field instances 870 which correspond to the field elements 845 of the form. Each field instance has an associated value 871, whose type depends on the type of the corresponding field element. Each field value records input through a
- 10 particular printed form instance, i.e. through one or more printed netpages. The form class diagram is shown in Figure 32.

- Each form instance has a status 872 which indicates whether the form is active, frozen, submitted, void or expired. A form is active when first printed. A form becomes frozen once it is signed. A form becomes submitted once one of its submission hyperlinks has
- 15 been activated, unless the hyperlink has its “submit delta” attribute set. A form becomes void when the user invokes a void form, reset form or duplicate form page command. A form expires when the time the form has been active exceeds the form’s specified lifetime. While the form is active, form input is allowed. Input through a form which is not active is instead captured in the background field 833 of the relevant page instance.
- 20 When the form is active or frozen, form submission is allowed. Any attempt to submit a form when the form is not active or frozen is rejected, and instead elicits a form status report.

- Each form instance is preferably associated (at 59) with any form instances derived from it, thus providing a version history. This allows all but the latest version of a form in a
- 25 particular time period to be excluded from a search.

All input is captured as digital ink. Digital ink 873 consists of a set of time-stamped stroke groups 874, each of which consists of a set of styled strokes 875. Each stroke consists of a set of time-stamped pen positions 876, each of which also includes pen orientation and nib force. The digital ink class diagram is shown in Figure 33.

- 30 A field element 845 can be a checkbox field 877, a text field 878, a drawing field 879, or

a signature field 880. The field element class diagram is shown in Figure 34. Any digital ink captured in a field's zone 58 is assigned to the field.

A checkbox field has an associated Boolean value 881, as shown in Figure 35. Any mark (a tick, a cross, a stroke, a fill zigzag, etc.) captured in a checkbox field's zone causes a true value to be assigned to the field's value.

A text field has an associated text value 882, as shown in Figure 36. Any digital ink captured in a text field's zone is automatically converted to text via online handwriting recognition, and the text is assigned to the field's value. Online handwriting recognition is well-understood (see, for example, Tappert, C., C.Y. Suen and T. Wakahara, "The State of the Art in On-Line Handwriting Recognition", IEEE Transactions on Pattern Analysis and Machine Intelligence, Vol.12, No.8, August 1990, the contents of which are herein incorporated by cross-reference). Specializations of text fields include date and number fields.

A signature field has an associated digital signature value 883, as shown in Figure 37. Any digital ink captured in a signature field's zone is automatically verified with respect to the identity of the owner of the pen, and a digital signature of the content of the form of which the field is part is generated and assigned to the field's value. The digital signature is generated using the pen user's private signature key specific to the application which owns the form. Online signature verification is well-understood (see, for example, Plamondon, R. and G. Lorette, "Automatic Signature Verification and Writer Identification – The State of the Art", Pattern Recognition, Vol.22, No.2, 1989, the contents of which are herein incorporated by cross-reference).

A field element is hidden if its "hidden" attribute is set. A hidden field element does not have an input zone on a page and does not accept input. It can have an associated field value which is included in the form data when the form containing the field is submitted. "Editing" commands, such as strike-throughs indicating deletion, can also be recognized in form fields.

Because the handwriting recognition algorithm works "online" (i.e. with access to the dynamics of the pen movement), rather than "offline" (i.e. with access only to a bitmap of pen markings), it can recognize run-on discretely-written characters with relatively

high accuracy, without a writer-dependent training phase. A writer-dependent model of handwriting is automatically generated over time, however, and can be generated up-front if necessary,

Digital ink, as already stated, consists of a sequence of strokes. Any stroke which starts in a particular element's zone is appended to that element's digital ink stream, ready for interpretation. Any stroke not appended to an object's digital ink stream is appended to the background field's digital ink stream.

Digital ink captured in the background field is interpreted as a selection gesture. Circumscription of one or more objects is generally interpreted as a selection of the circumscribed objects, although the actual interpretation is application-specific.

Table 2 summarizes these various pen interactions with a netpage.

**Table 2 - Summary of pen interactions with a netpage**

Object	Type	Pen input	Action
Hyperlink	General	Click	Submit action to application
	Form	Click	Submit form to application
	Selection	Click	Submit selection to application
Form field	Checkbox	Any mark	Assign true to field
	Text	Handwriting	Convert digital ink to text; assign text to field
	Drawing	Digital ink	Assign digital ink to field
	Signature	Signature	Verify digital ink signature; generate digital signature of form; assign digital signature to field
None	-	Circumscription	Assign digital ink to current selection

The system maintains a current selection for each pen. The selection consists simply of

the most recent stroke captured in the background field. The selection is cleared after an inactivity timeout to ensure predictable behavior.

The raw digital ink captured in every field is retained on the netpage page server and is optionally transmitted with the form data when the form is submitted to the application.

- 5 This allows the application to interrogate the raw digital ink should it suspect the original conversion, such as the conversion of handwritten text. This can, for example, involve human intervention at the application level for forms which fail certain application-specific consistency checks. As an extension to this, the entire background area of a form can be designated as a drawing field. The application can then decide, on the basis of the
- 10 presence of digital ink outside the explicit fields of the form, to route the form to a human operator, on the assumption that the user may have indicated amendments to the filled-in fields outside of those fields.

- Figure 38 shows a flowchart of the process of handling pen input relative to a netpage. The process consists of receiving (at 884) a stroke from the pen; identifying (at 885) the
- 15 page instance 830 to which the page ID 50 in the stroke refers; retrieving (at 886) the page description 5; identifying (at 887) a formatted element 839 whose zone 58 the stroke intersects; determining (at 888) whether the formatted element corresponds to a field element, and if so appending (at 892) the received stroke to the digital ink of the field value 871, interpreting (at 893) the accumulated digital ink of the field, and
- 20 determining (at 894) whether the field is part of a hyperlinked group 866 and if so activating (at 895) the associated hyperlink; alternatively determining (at 889) whether the formatted element corresponds to a hyperlink element and if so activating (at 895) the corresponding hyperlink; alternatively, in the absence of an input field or hyperlink, appending (at 890) the received stroke to the digital ink of the background field 833; and
- 25 copying (at 891) the received stroke to the current selection 826 of the current pen, as maintained by the registration server.

- Figure 38a shows a detailed flowchart of step 893 in the process shown in Figure 38, where the accumulated digital ink of a field is interpreted according to the type of the field. The process consists of determining (at 896) whether the field is a checkbox and
- 30 (at 897) whether the digital ink represents a checkmark, and if so assigning (at 898) a true value to the field value; alternatively determining (at 899) whether the field is a text

field and if so converting (at 900) the digital ink to computer text, with the help of the appropriate registration server, and assigning (at 901) the converted computer text to the field value; alternatively determining (at 902) whether the field is a signature field and if so verifying (at 903) the digital ink as the signature of the pen's owner, with the help of the appropriate registration server, creating (at 904) a digital signature of the contents of the corresponding form, also with the help of the registration server and using the pen owner's private signature key relating to the corresponding application, and assigning (at 905) the digital signature to the field value.

### 1.7.3 Page Server Commands

10 A page server command is a command which is handled locally by the page server. It operates directly on form, page and document instances.

A page server command 907 can be a void form command 908, a duplicate form command 909, a reset form command 910, a get form status command 911, a duplicate page command 912, a reset page command 913, a get page status command 914, a duplicate document command 915, a reset document command 916, or a get document status command 917, as shown in Figure 39.

A void form command voids the corresponding form instance. A duplicate form command voids the corresponding form instance and then produces an active printed copy of the current form instance with field values preserved. The copy contains the same hyperlink transaction IDs as the original, and so is indistinguishable from the original to an application. A reset form command voids the corresponding form instance and then produces an active printed copy of the form instance with field values discarded. The copy contains the same hyperlink transaction IDs as the original. A get form status command produces a printed report on the status of the corresponding form instance, including who published it, when it was printed, for whom it was printed, and the form status of the form instance.

Since a form hyperlink instance contains a transaction ID, the application has to be involved in producing a new form instance. A button requesting a new form instance is therefore typically implemented as a hyperlink.

30 A duplicate page command produces a printed copy of the corresponding page instance

with the background field value preserved. If the page contains a form or is part of a form, then the duplicate page command is interpreted as a duplicate form command. A reset page command produces a printed copy of the corresponding page instance with the background field value discarded. If the page contains a form or is part of a form, then  
5 the reset page command is interpreted as a reset form command. A get page status command produces a printed report on the status of the corresponding page instance, including who published it, when it was printed, for whom it was printed, and the status of any forms it contains or is part of.

The netpage logo which appears on every netpage is usually associated with a duplicate  
10 page element in the preferred implementation of the invention.

When a page instance is duplicated with field values preserved, field values are printed in their native form, i.e. a checkmark appears as a standard checkmark graphic, and text appears as typeset text. Only drawings and signatures appear in their original form, with a signature preferably accompanied by, or alternatively replaced by, a standard graphic  
15 indicating successful signature verification.

A duplicate document command produces a printed copy of the corresponding document instance with background field values preserved. If the document contains any forms, then the duplicate document command duplicates the forms in the same way a duplicate form command does. A reset document command produces a printed copy of the  
20 corresponding document instance with background field values discarded. If the document contains any forms, then the reset document command resets the forms in the same way a reset form command does. A get document status command produces a printed report on the status of the corresponding document instance, including who published it, when it was printed, for whom it was printed, and the status of any forms it  
25 contains.

If the page server command's "on selected" attribute is set, then the command operates on the page identified by the pen's current selection rather than on the page containing the command. This allows a menu of page server commands to be printed. If the target page doesn't contain a page server command element for the designated page server  
30 command, then the command is ignored.

An application can provide application-specific handling by embedding the relevant page server command element in a hyperlinked group. The page server activates the hyperlink associated with the hyperlinked group rather than executing the page server command.

- 5 A page server command element is hidden if its “hidden” attribute is set. A hidden command element does not have an input zone on a page and so cannot be activated directly by a user. It can, however, be activated via a page server command embedded in a different page, if that page server command has its “on selected” attribute set.

### 1.8 STANDARD FEATURES OF NETPAGES

- 10 In the preferred form, each netpage is printed with the netpage logo at the bottom to indicate that it is a netpage and therefore has interactive properties. The logo also acts as a copy button. In most cases “clicking” the logo produces a copy of the page. In the case of a form, the button produces a copy of the entire form. And in the case of a secure document, such as a ticket or coupon, the button elicits an explanatory note or advertising page.
- 15 The default single-page copy function is handled directly by the relevant netpage page server. Special copy functions are handled by linking the logo button to an application.

### 1.9 USER HELP SYSTEM

In a preferred embodiment, the netpage printer has a single button labeled “Help”. When pressed it elicits a single page of information, including:

- 20 • status of printer connection
- status of printer consumables
- top-level help menu
- document function menu
- top-level netpage network directory
- 25 The help menu provides a hierarchical manual on how to use the netpage system.

The document function menu includes the following functions:

- print a copy of a document

- print a clean copy of a form
- print the status of a document

A document function is initiated by simply pressing the button and then touching any page of the document. The status of a document indicates who published it and when, to whom it was delivered, and to whom and when it was subsequently submitted as a form.

The netpage network directory allows the user to navigate the hierarchy of publications and services on the network. As an alternative, the user can call the netpage network “900” number “yellow pages” and speak to a human operator. The operator can locate the desired document and route it to the user’s printer. Depending on the document type, the publisher or the user pays the small “yellow pages” service fee.

The help page is obviously unavailable if the printer is unable to print. In this case the “error” light is lit and the user can request remote diagnosis over the network.

## **2 PERSONALIZED PUBLICATION MODEL**

In the following description, news is used as a canonical publication example to illustrate personalization mechanisms in the netpage system. Although news is often used in the limited sense of newspaper and newsmagazine news, the intended scope in the present context is wider.

In the netpage system, the editorial content and the advertising content of a news publication are personalized using different mechanisms. The editorial content is personalized according to the reader’s explicitly stated and implicitly captured interest profile. The advertising content is personalized according to the reader’s locality and demographic.

### **2.1 EDITORIAL PERSONALIZATION**

A subscriber can draw on two kinds of news sources: those that deliver news publications, and those that deliver news streams. While news publications are aggregated and edited by the publisher, news streams are aggregated either by a news publisher or by a specialized news aggregator. News publications typically correspond to traditional newspapers and newsmagazines, while news streams can be many and varied:

a “raw” news feed from a news service, a cartoon strip, a freelance writer’s column, a friend’s bulletin board, or the reader’s own e-mail.

The netpage publication server supports the publication of edited news publications as well as the aggregation of multiple news streams. By handling the aggregation and hence  
5 the formatting of news streams selected directly by the reader, the server is able to place advertising on pages over which it otherwise has no editorial control.

The subscriber builds a daily newspaper by selecting one or more contributing news publications, and creating a personalized version of each. The resulting daily editions are printed and bound together into a single newspaper. The various members of a  
10 household typically express their different interests and tastes by selecting different daily publications and then customizing them.

For each publication, the reader optionally selects specific sections. Some sections appear daily, while others appear weekly. The daily sections available from The New York Times online, for example, include “Page One Plus”, “National”, “International”,  
15 “Opinion”, “Business”, “Arts/Living”, “Technology”, and “Sports”. The set of available sections is specific to a publication, as is the default subset.

The reader can extend the daily newspaper by creating custom sections, each one drawing on any number of news streams. Custom sections might be created for e-mail and friends’ announcements (“Personal”), or for monitoring news feeds for specific  
20 topics (“Alerts” or “Clippings”).

For each section, the reader optionally specifies its size, either qualitatively (e.g. short, medium, or long), or numerically (i.e. as a limit on its number of pages), and the desired proportion of advertising, either qualitatively (e.g. high, normal, low, none), or numerically (i.e. as a percentage).

25 The reader also optionally expresses a preference for a large number of shorter articles or a small number of longer articles. Each article is ideally written (or edited) in both short and long forms to support this preference.

An article may also be written (or edited) in different versions to match the expected sophistication of the reader, for example to provide children’s and adults’ versions. The  
30 appropriate version is selected according to the reader’s age. The reader can specify a

“reading age” which takes precedence over their biological age.

The articles which make up each section are selected and prioritized by the editors, and each is assigned a useful lifetime. By default they are delivered to all relevant subscribers, in priority order, subject to space constraints in the subscribers’ editions.

- 5 In sections where it is appropriate, the reader may optionally enable collaborative filtering. This is then applied to articles which have a sufficiently long lifetime. Each article which qualifies for collaborative filtering is printed with rating buttons at the end of the article. The buttons can provide an easy choice (e.g. “liked” and “disliked”), making it more likely that readers will bother to rate the article.

- 10 Articles with high priorities and short lifetimes are therefore effectively considered essential reading by the editors and are delivered to most relevant subscribers.

The reader optionally specifies a serendipity factor, either qualitatively (e.g. do or don’t surprise me), or numerically. A high serendipity factor lowers the threshold used for matching during collaborative filtering. A high factor makes it more likely that the

- 15 corresponding section will be filled to the reader’s specified capacity. A different serendipity factor can be specified for different days of the week.

The reader also optionally specifies topics of particular interest within a section, and this modifies the priorities assigned by the editors.

- 20 The speed of the reader’s Internet connection affects the quantity and quality at which images can be delivered. The reader optionally specifies a preference for fewer images or smaller images or both. If the number or size of images is not reduced, then images may be delivered at lower quality (i.e. at lower resolution or with greater compression). Alternatively all three of the quantity, size and quality of images delivered may be adjusted.

- 25 At a global level, the reader specifies how quantities, dates, times and monetary values are localized. This involves specifying whether units are imperial or metric, a local time zone and time format, and a local currency, and whether the localization consist of *in situ* translation or annotation. These preferences are derived from the reader’s locality by default.

- 30 To reduce reading difficulties caused by poor eyesight, the reader optionally specifies a

global preference for a larger presentation. Both text and images are scaled accordingly, and less information is accommodated on each page.

The language in which a news publication is published, and its corresponding text encoding, is a property of the publication and not a preference expressed by the user.

- 5 However, the netpage system can be configured to provide automatic translation services in various guises.

## 2.2 ADVERTISING LOCALIZATION AND TARGETING

- The personalization of the editorial content directly affects the advertising content, because advertising is typically placed to exploit the editorial context. Travel ads, for example, are more likely to appear in a travel section than elsewhere. The value of the editorial content to an advertiser (and therefore to the publisher) lies in its ability to attract large numbers of readers with the right demographics.
- 10

- Effective advertising is placed on the basis of locality and demographics. Locality determines proximity to particular services, retailers etc., and particular interests and concerns associated with the local community and environment. Demographics determine general interests and preoccupations as well as likely spending patterns.
- 15

A news publisher's most profitable product is advertising "space", a multi-dimensional entity determined by the publication's geographic coverage, the size of its readership, its readership demographics, and the page area available for advertising.

- 20 In the netpage system, the netpage publication server computes the approximate multi-dimensional size of a publication's saleable advertising space on a per-section basis, taking into account the publication's geographic coverage, the section's readership, the size of each reader's section edition, each reader's advertising proportion, and each reader's demographic.

- 25 In comparison with other media, the netpage system allows the advertising space to be defined in greater detail, and allows smaller pieces of it to be sold separately. It therefore allows it to be sold at closer to its true value.

For example, the same advertising "slot" can be sold in varying proportions to several advertisers, with individual readers' pages randomly receiving the advertisement of one

advertiser or another, overall preserving the proportion of space sold to each advertiser.

The netpage system allows advertising to be linked directly to detailed product information and online purchasing. It therefore raises the intrinsic value of the advertising space.

- 5 Because personalization and localization are handled automatically by netpage publication servers, an advertising aggregator can provide arbitrarily broad coverage of both geography and demographics. The subsequent disaggregation is efficient because it is automatic. This makes it more cost-effective for publishers to deal with advertising aggregators than to directly capture advertising. Even though the advertising aggregator  
10 is taking a proportion of advertising revenue, publishers may find the change profit-neutral because of the greater efficiency of aggregation. The advertising aggregator acts as an intermediary between advertisers and publishers, and may place the same advertisement in multiple publications.

- It is worth noting that ad placement in a netpage publication can be more complex than  
15 ad placement in the publication's traditional counterpart, because the publication's advertising space is more complex. While ignoring the full complexities of negotiations between advertisers, advertising aggregators and publishers, the preferred form of the netpage system provides some automated support for these negotiations, including support for automated auctions of advertising space. Automation is particularly desirable  
20 for the placement of advertisements which generate small amounts of income, such as small or highly localized advertisements.

- Once placement has been negotiated, the aggregator captures and edits the advertisement and records it on a netpage ad server. Correspondingly, the publisher records the ad placement on the relevant netpage publication server. When the netpage publication  
25 server lays out each user's personalized publication, it picks the relevant advertisements from the netpage ad server.

## 2.3 USER PROFILES

### 2.3.1 Information Filtering

The personalization of news and other publications relies on an assortment of user-

specific profile information, including:

- publication customizations
  - collaborative filtering vectors
  - contact details
- 5 • presentation preferences

The customization of a publication is typically publication-specific, and so the customization information is maintained by the relevant netpage publication server.

- A collaborative filtering vector consists of the user's ratings of a number of news items. It is used to correlate different users' interests for the purposes of making
- 10 recommendations. Although there are benefits to maintaining a single collaborative filtering vector independently of any particular publication, there are two reasons why it is more practical to maintain a separate vector for each publication: there is likely to be more overlap between the vectors of subscribers to the same publication than between those of subscribers to different publications; and a publication is likely to want to
- 15 present its users' collaborative filtering vectors as part of the value of its brand, not to be found elsewhere. Collaborative filtering vectors are therefore also maintained by the relevant netpage publication server.

Contact details, including name, street address, ZIP Code, state, country, telephone numbers, are global by nature, and are maintained by a netpage registration server.

- 20 Presentation preferences, including those for quantities, dates and times, are likewise global and maintained in the same way.

- The localization of advertising relies on the locality indicated in the user's contact details, while the targeting of advertising relies on personal information such as date of birth, gender, marital status, income, profession, education, or qualitative derivatives
- 25 such as age range and income range.

For those users who choose to reveal personal information for advertising purposes, the information is maintained by the relevant netpage registration server. In the absence of such information, advertising can be targeted on the basis of the demographic associated with the user's ZIP or ZIP+4 Code.

Each user, pen, printer, application provider and application is assigned its own unique identifier, and the netpage registration server maintains the relationships between them, as shown in Figures 21, 22, 23 and 24. For registration purposes, a publisher is a special kind of application provider, and a publication is a special kind of application.

- 5 Each user 800 may be authorized to use any number of printers 802, and each printer may allow any number of users to use it. Each user has a single default printer (at 66), to which periodical publications are delivered by default, whilst pages printed on demand are delivered to the printer through which the user is interacting. The server keeps track of which publishers a user has authorized to print to the user's default printer. A  
10 publisher does not record the ID of any particular printer, but instead resolves the ID when it is required.

- When a user subscribes 808 to a publication 807, the publisher 806 (i.e. application provider 803) is authorized to print to a specified printer or the user's default printer. This authorization can be revoked at any time by the user. Each user may have several  
15 pens 801, but a pen is specific to a single user. If a user is authorized to use a particular printer, then that printer recognizes any of the user's pens.

The pen ID is used to locate the corresponding user profile maintained by a particular netpage registration server, via the DNS in the usual way.

- A Web terminal 809 can be authorized to print on a particular netpage printer, allowing  
20 Web pages and netpage documents encountered during Web browsing to be conveniently printed on the nearest netpage printer.

- The netpage system can collect, on behalf of a printer provider, fees and commissions on income earned through publications printed on the provider's printers. Such income can include advertising fees, click-through fees, e-commerce commissions, and transaction  
25 fees. If the printer is owned by the user, then the user is the printer provider.

- Each user also has a netpage account 820 which is used to accumulate micro-debits and credits (such as those described in the preceding paragraph); contact details 815, including name, address and telephone numbers; global preferences 816, including privacy, delivery and localization settings; any number of biometric records 817,  
30 containing the user's encoded signature 818, fingerprint 819 etc; a handwriting model

819 automatically maintained by the system; and SET payment card accounts 821 with which e-commerce payments can be made.

### 2.3.2 Favorites List

5 A netpage user can maintain a list 922 of “favorites” - links to useful documents etc. on the netpage network. The list is maintained by the system on the user’s behalf. It is organized as a hierarchy of folders 924, a preferred embodiment of which is shown in the class diagram in Figure 41.

### 2.3.3 History List

10 The system preferably maintains a history list 929 on each user’s behalf, containing links to documents etc. accessed by the user through the netpage system. It is organized as a date-ordered list, a preferred embodiment of which is shown in the class diagram in Figure 42.

## 2.4 INTELLIGENT PAGE LAYOUT

15 The netpage publication server automatically lays out the pages of each user’s personalized publication on a section-by-section basis. Since most advertisements are in the form of pre-formatted rectangles, they are placed on the page before the editorial content.

20 The advertising ratio for a section can be achieved with wildly varying advertising ratios on individual pages within the section, and the ad layout algorithm exploits this. The algorithm is configured to attempt to co-locate closely tied editorial and advertising content, such as placing ads for roofing material specifically within the publication because of a special feature on do-it-yourself roofing repairs.

The editorial content selected for the user, including text and associated images and graphics, is then laid out according to various aesthetic rules.

25 The entire process, including the selection of ads and the selection of editorial content, must be iterated once the layout has converged, to attempt to more closely achieve the user’s stated section size preference. The section size preference can, however, be matched *on average* over time, allowing significant day-to-day variations.

## 2.5 DOCUMENT FORMAT

Once the document is laid out, it is encoded for efficient distribution and persistent storage on the netpage network.

The primary efficiency mechanism is the separation of information specific to a single user's edition and information shared between multiple users' editions. The specific information consists of the page layout. The shared information consists of the objects to which the page layout refers, including images, graphics, and pieces of text.

A text object contains fully-formatted text, preferably represented in the Extensible Markup Language (XML) using the Extensible Stylesheet Language (XSL). XSL provides precise control over text formatting independently of the region into which the text is being set, which in this case is being provided by the layout. The text object contains embedded language codes to enable automatic translation, and embedded hyphenation hints to aid with paragraph formatting.

An image object encodes an image, preferably in the JPEG 2000 wavelet-based compressed image format. A graphic object encodes a 2D graphic, preferably in Scalable Vector Graphics (SVG) format. Other formats may be used for text, images and graphics.

The layout itself consists of a series of placed image and graphic objects, linked textflow objects through which text objects flow, hyperlinks and input fields as described above, and watermark regions. These layout objects are summarized in Table 3. The layout uses a compact format suitable for efficient distribution and storage.

**Table 3 - netpage layout objects**

Layout object	Attribute	Format of linked object
Image	Position	-
	Image object ID	JPEG 2000
Graphic	Position	-

	Graphic object ID	SVG
Textflow	Textflow ID	-
	Zone	-
	Optional text object ID	XML/XSL
Hyperlink	Type	-
	Zone	-
	Application ID, etc.	-
Field	Type	-
	Meaning	-
	Zone	-
Watermark	Zone	-

## 2.6 DOCUMENT DISTRIBUTION

As described above, for purposes of efficient distribution and persistent storage on the netpage network, a user-specific page layout is separated from the shared objects to which it refers.

When a subscribed publication is ready to be distributed, the netpage publication server allocates, with the help of the netpage ID server 12, a unique ID for each page, page instance, document, and document instance.

The server computes a set of optimized subsets of the shared content and creates a multicast channel for each subset, and then tags each user-specific layout with the names of the multicast channels which will carry the shared content used by that layout. The server then pointcasts each user's layouts to that user's printer via the appropriate page server, and when the pointcasting is complete, multicasts the shared content on the specified channels. After receiving its pointcast, each page server and printer subscribes to the multicast channels specified in the page layouts. During the multicasts, each page server and printer extracts from the multicast streams those objects referred to by its page

layouts. The page servers persistently archive the received page layouts and shared content. Other techniques for distributing the data may be used.

Once a printer has received all the objects to which its page layouts refer, the printer re-creates the fully-populated layout and then rasterizes and prints it.

- 5 Under normal circumstances, the printer prints pages faster than they can be delivered. Assuming a quarter of each page is covered with images, the average page has a size of less than 400KB. The printer can therefore hold in excess of 100 such pages in its internal 64MB memory, allowing for temporary buffers etc. The printer prints at a rate of one page per second. This is equivalent to 400KB or about 3Mbit of page data per  
10 second, which is similar to the highest expected rate of page data delivery over a broadband network.

Even under abnormal circumstances, such as when the printer runs out of paper, it is likely that the user will be able to replenish the paper supply before the printer's 100-page internal storage capacity is exhausted.

- 15 However, if the printer's internal memory does fill up, then the printer will be unable to make use of a multicast when it first occurs. The netpage publication server therefore allows printers to submit requests for re-multicasts. When a critical number of requests is received or a timeout occurs, the server re-multicasts the corresponding shared objects.

- Once a document is printed, a printer can produce an exact duplicate at any time by  
20 retrieving its page layouts and contents from the relevant page server.

## 2.7 ON-DEMAND DOCUMENTS

When a netpage document is requested on demand, it can be personalized and delivered in much the same way as a periodical. However, since there is no shared content, delivery is made directly to the requesting printer without the use of multicast.

- 25 When a non-netpage document is requested on demand, it is not personalized, and it is delivered via a designated netpage formatting server which reformats it as a netpage document. A netpage formatting server is a special instance of a netpage publication server. The netpage formatting server has knowledge of various Internet document formats, including Adobe's Portable Document Format (PDF), and Hypertext Markup

Language (HTML). In the case of HTML, it can make use of the higher resolution of the printed page to present Web pages in a multi-column format, with a table of contents. It can automatically include all Web pages directly linked to the requested page. The user can tune this behavior via a preference.

- 5 The netpage formatting server makes standard netpage behavior, including interactivity and persistence, available on any Internet document, no matter what its origin and format. It hides knowledge of different document formats from both the netpage printer and the netpage page server, and hides knowledge of the netpage system from Web servers.

## 10 3 SECURITY

### 3.1 CRYPTOGRAPHY

- Cryptography is used to protect sensitive information, both in storage and in transit, and to authenticate parties to a transaction. There are two classes of cryptography in widespread use: secret-key cryptography and public-key cryptography. The netpage network uses both classes of cryptography.

Secret-key cryptography, also referred to as symmetric cryptography, uses the same key to encrypt and decrypt a message. Two parties wishing to exchange messages must first arrange to securely exchange the secret key.

- Public-key cryptography, also referred to as asymmetric cryptography, uses two encryption keys. The two keys are mathematically related in such a way that any message encrypted using one key can only be decrypted using the other key. One of these keys is then published, while the other is kept private. The public key is used to encrypt any message intended for the holder of the private key. Once encrypted using the public key, a message can only be decrypted using the private key. Thus two parties can securely exchange messages without first having to exchange a secret key. To ensure that the private key is secure, it is normal for the holder of the private key to generate the key pair.

Public-key cryptography can be used to create a digital signature. The holder of the private key can create a known hash of a message and then encrypt the hash using the

private key. Anyone can then verify that the encrypted hash constitutes the “signature” of the holder of the private key with respect to that particular message by decrypting the encrypted hash using the public key and verifying the hash against the message. If the signature is appended to the message, then the recipient of the message can verify both  
5 that the message is genuine and that it has not been altered in transit.

To make public-key cryptography work, there has to be a way to distribute public keys which prevents impersonation. This is normally done using certificates and certificate authorities. A certificate authority is a trusted third party which authenticates the connection between a public key and someone’s identity. The certificate authority  
10 verifies the person’s identity by examining identity documents, and then creates and signs a digital certificate containing the person’s identity details and public key. Anyone who trusts the certificate authority can use the public key in the certificate with a high degree of certainty that it is genuine. They just have to verify that the certificate has indeed been signed by the certificate authority, whose public key is well-known.

15 In most transaction environments, public-key cryptography is only used to create digital signatures and to securely exchange secret session keys. Secret-key cryptography is used for all other purposes.

In the following discussion, when reference is made to the *secure* transmission of information between a netpage printer and a server, what actually happens is that the  
20 printer obtains the server’s certificate, authenticates it with reference to the certificate authority, uses the public key-exchange key in the certificate to exchange a secret session key with the server, and then uses the secret session key to encrypt the message data. A *session* key, by definition, can have an arbitrarily short lifetime.

### 3.2 NETPAGE PRINTER SECURITY

25 Each netpage printer is assigned a pair of unique identifiers at time of manufacture which are stored in read-only memory in the printer and in the netpage registration server database. The first ID 62 is public and uniquely identifies the printer on the netpage network. The second ID is secret and is used when the printer is first registered on the network.

30 When the printer connects to the netpage network for the first time after installation, it

creates a signature public/private key pair. It transmits the secret ID and the public key securely to the netpage registration server. The server compares the secret ID against the printer's secret ID recorded in its database, and accepts the registration if the IDs match. It then creates and signs a certificate containing the printer's public ID and public signature key, and stores the certificate in the registration database.

The netpage registration server acts as a certificate authority for netpage printers, since it has access to secret information allowing it to verify printer identity.

When a user subscribes to a publication, a record is created in the netpage registration server database authorizing the publisher to print the publication to the user's default printer or a specified printer. Every document sent to a printer via a page server is addressed to a particular user and is signed by the publisher using the publisher's private signature key. The page server verifies, via the registration database, that the publisher is authorized to deliver the publication to the specified user. The page server verifies the signature using the publisher's public key, obtained from the publisher's certificate stored in the registration database.

The netpage registration server accepts requests to add printing authorizations to the database, so long as those requests are initiated via a pen registered to the printer.

### 3.3 NETPAGE PEN SECURITY

Each netpage pen is assigned a unique identifier at time of manufacture which is stored in read-only memory in the pen and in the netpage registration server database. The pen ID 61 uniquely identifies the pen on the netpage network.

A netpage pen can "know" a number of netpage printers, and a printer can "know" a number of pens. A pen communicates with a printer via a radio frequency signal whenever it is within range of the printer. Once a pen and printer are registered, they regularly exchange session keys. Whenever the pen transmits digital ink to the printer, the digital ink is always encrypted using the appropriate session key. Digital ink is never transmitted in the clear.

A pen stores a session key for every printer it knows, indexed by printer ID, and a printer stores a session key for every pen it knows, indexed by pen ID. Both have a large but

finite storage capacity for session keys, and will forget a session key on a least-recently-used basis if necessary.

When a pen comes within range of a printer, the pen and printer discover whether they know each other. If they don't know each other, then the printer determines whether it is supposed to know the pen. This might be, for example, because the pen belongs to a user who is registered to use the printer. If the printer is meant to know the pen but doesn't, then it initiates the automatic pen registration procedure. If the printer isn't meant to know the pen, then it agrees with the pen to ignore it until the pen is placed in a charging cup, at which time it initiates the registration procedure.

10 In addition to its public ID, the pen contains a secret key-exchange key. The key-exchange key is also recorded in the netpage registration server database at time of manufacture. During registration, the pen transmits its pen ID to the printer, and the printer transmits the pen ID to the netpage registration server. The server generates a session key for the printer and pen to use, and securely transmits the session key to the  
15 printer. It also transmits a copy of the session key encrypted with the pen's key-exchange key. The printer stores the session key internally, indexed by the pen ID, and transmits the encrypted session key to the pen. The pen stores the session key internally, indexed by the printer ID.

Although a fake pen can impersonate a pen in the pen registration protocol, only a real  
20 pen can decrypt the session key transmitted by the printer.

When a previously unregistered pen is first registered, it is of limited use until it is linked to a user. A registered but "un-owned" pen is only allowed to be used to request and fill in netpage user and pen registration forms, to register a new user to which the new pen is automatically linked, or to add a new pen to an existing user.

25 The pen uses secret-key rather than public-key encryption because of hardware performance constraints in the pen.

### 3.4 SECURE DOCUMENTS

The netpage system supports the delivery of secure documents such as tickets and coupons. The netpage printer includes a facility to print watermarks, but will only do so

on request from publishers who are suitably authorized. The publisher indicates its authority to print watermarks in its certificate, which the printer is able to authenticate.

The “watermark” printing process uses an alternative dither matrix in specified “watermark” regions of the page. Back-to-back pages contain mirror-image watermark regions which coincide when printed. The dither matrices used in odd and even pages’ watermark regions are designed to produce an interference effect when the regions are viewed together, achieved by looking *through* the printed sheet.

The effect is similar to a watermark in that it is not visible when looking at only one side of the page, and is lost when the page is copied by normal means.

- 10 Pages of secure documents cannot be copied using the built-in netpage copy mechanism described in Section 1.9 above. This extends to copying netpages on netpage-aware photocopiers.

Secure documents are typically generated as part of e-commerce transactions. They can therefore include the user’s photograph which was captured when the user registered biometric information with the netpage registration server, as described in Section 2.

When presented with a secure netpage document, the recipient can verify its authenticity by requesting its status in the usual way. The unique ID of a secure document is only valid for the lifetime of the document, and secure document IDs are allocated non-contiguously to prevent their prediction by opportunistic forgers. A secure document verification pen can be developed with built-in feedback on verification failure, to support easy point-of-presentation document verification.

Clearly neither the watermark nor the user’s photograph are secure in a cryptographic sense. They simply provide a significant obstacle to casual forgery. Online document verification, particularly using a verification pen, provides an added level of security where it is needed, but is still not entirely immune to forgeries.

### 3.5 NON-REPUDIATION

In the netpage system, forms submitted by users are delivered reliably to forms handlers and are persistently archived on netpage page servers. It is therefore impossible for recipients to repudiate delivery.

E-commerce payments made through the system, as described in Section 4, are also impossible for the payee to repudiate.

## **4 ELECTRONIC COMMERCE MODEL**

### **4.1 SECURE ELECTRONIC TRANSACTION (SET)**

- 5 The netpage system uses the Secure Electronic Transaction (SET) system as one of its payment systems. SET, having been developed by MasterCard and Visa, is organized around payment cards, and this is reflected in the terminology. However, much of the system is independent of the type of accounts being used. Other payment systems may also be used.
- 10 In SET, cardholders and merchants register with a certificate authority and are issued with certificates containing their public signature keys. The certificate authority verifies a cardholder's registration details with the card issuer as appropriate, and verifies a merchant's registration details with the acquirer as appropriate. Cardholders and merchants store their respective private signature keys securely on their computers.
- 15 During the payment process, these certificates are used to mutually authenticate a merchant and cardholder, and to authenticate them both to the payment gateway.

SET has not yet been adopted widely, partly because cardholder maintenance of keys and certificates is considered burdensome. Interim solutions which maintain cardholder keys and certificates on a server and give the cardholder access via a password have met with

20 some success.

### **4.2 SET PAYMENTS**

In the netpage system the netpage registration server acts as a proxy for the netpage user (i.e. the cardholder) in SET payment transactions.

- The netpage system uses biometrics to authenticate the user and authorize SET
- 25 payments. Because the system is pen-based, the biometric used is the user's on-line signature, consisting of time-varying pen position and pressure. A fingerprint biometric can also be used by designing a fingerprint sensor into the pen, although at a higher cost. The type of biometric used only affects the capture of the biometric, not the

authorization aspects of the system.

The first step to being able to make SET payments is to register the user's biometric with the netpage registration server. This is done in a controlled environment, for example a bank, where the biometric can be captured at the same time as the user's identity is  
5 verified. The biometric is captured and stored in the registration database, linked to the user's record. The user's photograph is also optionally captured and linked to the record. The SET cardholder registration process is completed, and the resulting private signature key and certificate are stored in the database. The user's payment card information is also stored, giving the netpage registration server enough information to act as the user's  
10 proxy in any SET payment transaction.

When the user eventually supplies the biometric to complete a payment, for example by signing a netpage order form, the printer securely transmits the order information, the pen ID and the biometric data to the netpage registration server. The server verifies the biometric with respect to the user identified by the pen ID, and from then on acts as the  
15 user's proxy in completing the SET payment transaction.

### 4.3 MICRO-PAYMENTS

The netpage system includes a mechanism for micro-payments, to allow the user to be conveniently charged for printing low-cost documents on demand and for copying copyright documents, and possibly also to allow the user to be reimbursed for expenses  
20 incurred in printing advertising material. The latter depends on the level of subsidy already provided to the user.

When the user registers for e-commerce, a network account is established which aggregates micro-payments. The user receives a statement on a regular basis, and can settle any outstanding debit balance using the standard payment mechanism.

25 The network account can be extended to aggregate subscription fees for periodicals, which would also otherwise be presented to the user in the form of individual statements.

### 4.4 TRANSACTIONS

When a user requests a netpage in a particular application context, the application is able to embed a user-specific transaction ID 55 in the page. Subsequent input through the

page is tagged with the transaction ID, and the application is thereby able to establish an appropriate context for the user's input.

- When input occurs through a page which is not user-specific, however, the application must use the user's unique identity to establish a context. A typical example involves
- 5 adding items from a pre-printed catalog page to the user's virtual "shopping cart". To protect the user's privacy, however, the unique user ID 60 known to the netpage system is preferably not divulged to applications. This is to prevent different application providers from easily correlating independently accumulated behavioral data.

- The netpage registration server instead maintains an anonymous relationship between a
- 10 user and an application via a unique alias ID 65, as shown in Figure 24. Whenever the user activates a hyperlink tagged with the "registered" attribute, the netpage page server asks the netpage registration server to translate the associated application ID 64, together with the pen ID 61, into an alias ID 65. The alias ID is then submitted to the hyperlink's application.

- 15 The application maintains state information indexed by alias ID, and is able to retrieve user-specific state information without knowledge of the global identity of the user.

The system also maintains an independent certificate and private signature key for each of a user's applications, to allow it to sign application transactions on behalf of the user using only application-specific information.

- 20 To assist the system in routing product bar code (UPC) "hyperlink" activations, the system records a favorite application on behalf of the user for any number of product types.

- Each application is associated with an application provider, and the system maintains an account on behalf of each application provider, to allow it to credit and debit the
- 25 provider for click-through fees etc.

An application provider can be a publisher of periodical subscribed content. The system records the user's willingness to receive the subscribed publication, as well as the expected frequency of publication.

#### 4.5 RESOURCE DESCRIPTIONS AND COPYRIGHT

A preferred embodiment of a resource description class diagram is shown in Figure 40.

Each document and content object may be described by one or more resource descriptions 842. Resource descriptions preferably use the Dublin Core metadata element set, which is designed to facilitate discovery of electronic resources. Dublin Core metadata conforms to the World Wide Web Consortium (W3C) Resource Description Framework (RDF). Other metadata element sets may be used.

A resource description may identify rights holders 920. The netpage system automatically transfers copyright fees from users to rights holders when users print copyright content.

### 5 COMMUNICATIONS PROTOCOLS

A communications protocol defines an ordered exchange of messages between entities. In the netpage system, entities such as pens, printers and servers utilize a set of defined protocols to cooperatively handle user interaction with the netpage system.

Each protocol is illustrated by way of a sequence diagram in which the horizontal dimension is used to represent message flow and the vertical dimension is used to represent time. Each entity is represented by a rectangle containing the name of the entity and a vertical column representing the lifeline of the entity. During the time an entity exists, the lifeline is shown as a dashed line. During the time an entity is active, the lifeline is shown as a double line. Because the protocols considered here do not create or destroy entities, lifelines are generally cut short as soon as an entity ceases to participate in a protocol.

#### 5.1 SUBSCRIPTION DELIVERY PROTOCOL

A preferred embodiment of a subscription delivery protocol is shown in Figure 43.

A large number of users may subscribe to a periodical publication. Each user's edition may be laid out differently, but many users' editions will share common content such as text objects and image objects. The subscription delivery protocol therefore delivers document structures to individual printers via pointcast, but delivers shared content objects via multicast.

The application (i.e. publisher) first obtains a document ID 51 for each document from an ID server 12. It then sends each document structure, including its document ID and page descriptions, to the page server 10 responsible for the document's newly allocated ID. It includes its own application ID 64, the subscriber's alias ID 65, and the relevant set of multicast channel names. It signs the message using its private signature key.

The page server uses the application ID and alias ID to obtain from the registration server the corresponding user ID 60, the user's selected printer ID 62 (which may be explicitly selected for the application, or may be the user's default printer), and the application's certificate.

- 10 The application's certificate allows the page server to verify the message signature. The page server's request to the registration server fails if the application ID and alias ID don't together identify a subscription 808.

The page server then allocates document and page instance IDs and forwards the page descriptions, including page IDs 50, to the printer. It includes the relevant set of multicast channel names for the printer to listen to.

It then returns the newly allocated page IDs to the application for future reference.

- Once the application has distributed all of the document structures to the subscribers' selected printers via the relevant page servers, it multicasts the various subsets of the shared objects on the previously selected multicast channels. Both page servers and printers monitor the appropriate multicast channels and receive their required content objects. They are then able to populate the previously pointcast document structures. This allows the page servers to add complete documents to their databases, and it allows the printers to print the documents.

## 5.2 HYPERLINK ACTIVATION PROTOCOL

- 25 A preferred embodiment of a hyperlink activation protocol is shown in Figure 45.

When a user clicks on a netpage with a netpage pen, the pen communicates the click to the nearest netpage printer 601. The click identifies the page and a location on the page. The printer already knows the ID 61 of the pen from the pen connection protocol.

The printer determines, via the DNS, the network address of the page server 10a

handling the particular page ID 50. The address may already be in its cache if the user has recently interacted with the same page. The printer then forwards the pen ID, its own printer ID 62, the page ID and click location to the page server.

5 The page server loads the page description 5 identified by the page ID and determines which input element's zone 58, if any, the click lies in. Assuming the relevant input element is a hyperlink element 844, the page server then obtains the associated application ID 64 and link ID 54, and determines, via the DNS, the network address of the application server hosting the application 71.

10 The page server uses the pen ID 61 to obtain the corresponding user ID 60 from the registration server 11, and then allocates a globally unique hyperlink request ID 52 and builds a hyperlink request 934. The hyperlink request class diagram is shown in Figure 44. The hyperlink request records the IDs of the requesting user and printer, and identifies the clicked hyperlink instance 862. The page server then sends its own server ID 53, the hyperlink request ID, and the link ID to the application.

15 The application produces a response document according to application-specific logic, and obtains a document ID 51 from an ID server 12. It then sends the document to the page server 10b responsible for the document's newly allocated ID, together with the requesting page server's ID and the hyperlink request ID.

20 The second page server sends the hyperlink request ID and application ID to the first page server to obtain the corresponding user ID and printer ID 62. The first page server rejects the request if the hyperlink request has expired or is for a different application.

The second page server allocates document instance and page IDs 50, returns the newly allocated page IDs to the application, adds the complete document to its own database, and finally sends the page descriptions to the requesting printer.

25 The hyperlink instance may include a meaningful transaction ID 55, in which case the first page server includes the transaction ID in the message sent to the application. This allows the application to establish a transaction-specific context for the hyperlink activation.

30 If the hyperlink requires a user alias, i.e. its "alias required" attribute is set, then the first page server sends both the pen ID 61 and the hyperlink's application ID 64 to the

registration server 11 to obtain not just the user ID corresponding to the pen ID but also the alias ID 65 corresponding to the application ID and the user ID. It includes the alias ID in the message sent to the application, allowing the application to establish a user-specific context for the hyperlink activation.

### 5 5.3 HANDWRITING RECOGNITION PROTOCOL

When a user draws a stroke on a netpage with a netpage pen, the pen communicates the stroke to the nearest netpage printer. The stroke identifies the page and a path on the page.

The printer forwards the pen ID 61, its own printer ID 62, the page ID 50 and stroke path  
10 to the page server 10 in the usual way.

The page server loads the page description 5 identified by the page ID and determines which input element's zone 58, if any, the stroke intersects. Assuming the relevant input element is a text field 878, the page server appends the stroke to the text field's digital ink.

15 After a period of inactivity in the zone of the text field, the page server sends the pen ID and the pending strokes to the registration server 11 for interpretation. The registration server identifies the user corresponding to the pen, and uses the user's accumulated handwriting model 822 to interpret the strokes as handwritten text. Once it has converted the strokes to text, the registration server returns the text to the requesting page server.  
20 The page server appends the text to the text value of the text field.

### 5.4 SIGNATURE VERIFICATION PROTOCOL

Assuming the input element whose zone the stroke intersects is a signature field 880, the page server 10 appends the stroke to the signature field's digital ink.

After a period of inactivity in the zone of the signature field, the page server sends the  
25 pen ID 61 and the pending strokes to the registration server 11 for verification. It also sends the application ID 64 associated with the form of which the signature field is part, as well as the form ID 56 and the current data content of the form. The registration server identifies the user corresponding to the pen, and uses the user's dynamic signature biometric 818 to verify the strokes as the user's signature. Once it has verified the

signature, the registration server uses the application ID 64 and user ID 60 to identify the user's application-specific private signature key. It then uses the key to generate a digital signature of the form data, and returns the digital signature to the requesting page server. The page server assigns the digital signature to the signature field and sets the associated form's status to frozen.

The digital signature includes the alias ID 65 of the corresponding user. This allows a single form to capture multiple users' signatures.

### 5.5 FORM SUBMISSION PROTOCOL

A preferred embodiment of a form submission protocol is shown in Figure 46.

- 10 Form submission occurs via a form hyperlink activation. It thus follows the protocol defined in Section 5.2, with some form-specific additions.

In the case of a form hyperlink, the hyperlink activation message sent by the page server 10 to the application 71 also contains the form ID 56 and the current data content of the form. If the form contains any signature fields, then the application verifies each one by extracting the alias ID 65 associated with the corresponding digital signature and obtaining the corresponding certificate from the registration server 11.

### 5.6 COMMISSION PAYMENT PROTOCOL

A preferred embodiment of a commission payment protocol is shown in Figure 47.

- 20 In an e-commerce environment, fees and commissions may be payable from an application provider to a publisher on click-throughs, transactions and sales. Commissions on fees and commissions on commissions may also be payable from the publisher to the provider of the printer.

25 The hyperlink request ID 52 is used to route a fee or commission credit from the target application provider 70a (e.g. merchant) to the source application provider 70b (i.e. publisher), and from the source application provider 70b to the printer provider 72.

The target application receives the hyperlink request ID from the page server 10 when the hyperlink is first activated, as described in Section 5.2. When the target application needs to credit the source application provider, it sends the application provider credit to

the original page server together with the hyperlink request ID. The page server uses the hyperlink request ID to identify the source application, and sends the credit on to the relevant registration server 11 together with the source application ID 64, its own server ID 53, and the hyperlink request ID. The registration server credits the corresponding application provider's account 827. It also notifies the application provider.

If the application provider needs to credit the printer provider, it sends the printer provider credit to the original page server together with the hyperlink request ID. The page server uses the hyperlink request ID to identify the printer, and sends the credit on to the relevant registration server together with the printer ID. The registration server credits the corresponding printer provider account 814.

The source application provider is optionally notified of the identity of the target application provider, and the printer provider of the identity of the source application provider.

## **6. NETPAGE PEN DESCRIPTION**

### **6.1 PEN MECHANICS**

Referring to Figures 8 and 9, the pen, generally designated by reference numeral 101, includes a housing 102 in the form of a plastics molding having walls 103 defining an interior space 104 for mounting the pen components. The pen top 105 is in operation rotatably mounted at one end 106 of the housing 102. A semi-transparent cover 107 is secured to the opposite end 108 of the housing 102. The cover 107 is also of molded plastics, and is formed from semi-transparent material in order to enable the user to view the status LED 116 mounted within the housing 102. The cover 107 includes a main part 109 which substantially surrounds the end 108 of the housing 102 and a projecting portion 110 which projects back from the main part 109 and fits within a corresponding slot 111 formed in the walls 103 of the housing 102. A radio antenna 112 is mounted behind the projecting portion 110, within the housing 102. Screw threads 113 surrounding an aperture 113A on the cover 107 are arranged to receive a metal end piece 114, including corresponding screw threads 115. The metal end piece 114 is removable to enable ink cartridge replacement.

Also mounted within the cover 107 is a tri-color status LED 116 on a flex PCB 117. The antenna 112 is also mounted on the flex PCB 117. The status LED 116 is mounted at the top of the pen 101 for good all-around visibility.

The pen can operate both as a normal marking ink pen and as a non-marking stylus. An ink pen cartridge 118 with nib 119 and a stylus 120 with stylus nib 121 are mounted side by side within the housing 102. Either the ink cartridge nib 119 or the stylus nib 121 can be brought forward through open end 122 of the metal end piece 114, by rotation of the pen top 105. Respective slider blocks 123 and 124 are mounted to the ink cartridge 118 and stylus 120, respectively. A rotatable cam barrel 125 is secured to the pen top 105 in operation and arranged to rotate therewith. The cam barrel 125 includes a cam 126 in the form of a slot within the walls 181 of the cam barrel. Cam followers 127 and 128 projecting from slider blocks 123 and 124 fit within the cam slot 126. On rotation of the cam barrel 125, the slider blocks 123 or 124 move relative to each other to project either the pen nib 119 or stylus nib 121 out through the hole 122 in the metal end piece 114.

The pen 101 has three states of operation. By turning the top 105 through 90° steps, the three states are:

- Stylus 120 nib 121 out;
- Ink cartridge 118 nib 119 out; and
- Neither ink cartridge 118 nib 119 out nor stylus 120 nib 121 out.

A second flex PCB 129, is mounted on an electronics chassis 130 which sits within the housing 102. The second flex PCB 129 mounts an infrared LED 131 for providing infrared radiation for projection onto the surface. An image sensor 132 is provided mounted on the second flex PCB 129 for receiving reflected radiation from the surface. The second flex PCB 129 also mounts a radio frequency chip 133, which includes an RF transmitter and RF receiver, and a controller chip 134 for controlling operation of the pen 101. An optics block 135 (formed from molded clear plastics) sits within the cover 107 and projects an infrared beam onto the surface and receives images onto the image sensor 132. Power supply wires 136 connect the components on the second flex PCB 129 to battery contacts 137 which are mounted within the cam barrel 125. A terminal 138 connects to the battery contacts 137 and the cam barrel 125. A three volt

rechargeable battery 139 sits within the cam barrel 125 in contact with the battery contacts. An induction charging coil 140 is mounted about the second flex PCB 129 to enable recharging of the battery 139 via induction. The second flex PCB 129 also mounts an infrared LED 143 and infrared photodiode 144 for detecting displacement in  
5 the cam barrel 125 when either the stylus 120 or the ink cartridge 118 is used for writing, in order to enable a determination of the force being applied to the surface by the pen nib 119 or stylus nib 121. The IR photodiode 144 detects light from the IR LED 143 via reflectors (not shown) mounted on the slider blocks 123 and 124.

Rubber grip pads 141 and 142 are provided towards the end 108 of the housing 102 to  
10 assist gripping the pen 101, and top 105 also includes a clip 142 for clipping the pen 101 to a pocket.

## 6.2 PEN CONTROLLER

The pen 101 is arranged to determine the position of its nib (stylus nib 121 or ink cartridge nib 119) by imaging, in the infrared spectrum, an area of the surface in the  
15 vicinity of the nib. It records the location data from the nearest location tag, and is arranged to calculate the distance of the nib 121 or 119 from the location tag utilizing optics 135 and controller chip 134. The controller chip 134 calculates the orientation of the pen and the nib-to-tag distance from the perspective distortion observed on the imaged tag.

20 Utilizing the RF chip 133 and antenna 112 the pen 101 can transmit the digital ink data (which is encrypted for security and packaged for efficient transmission) to the computing system.

When the pen is in range of a receiver, the digital ink data is transmitted as it is formed. When the pen 101 moves out of range, digital ink data is buffered within the pen 101  
25 (the pen 101 circuitry includes a buffer arranged to store digital ink data for approximately 12 minutes of the pen motion on the surface) and can be transmitted later.

The controller chip 134 is mounted on the second flex PCB 129 in the pen 101. Figure 10 is a block diagram illustrating in more detail the architecture of the controller chip 134. Figure 10 also shows representations of the RF chip 133, the image sensor 132, the  
30 tri-color status LED 116, the IR illumination LED 131, the IR force sensor LED 143, and

the force sensor photodiode 144.

The pen controller chip 134 includes a controlling processor 145. Bus 146 enables the exchange of data between components of the controller chip 134. Flash memory 147 and a 512 KB DRAM 148 are also included. An analog-to-digital converter 149 is arranged  
5 to convert the analog signal from the force sensor photodiode 144 to a digital signal.

An image sensor interface 152 interfaces with the image sensor 132. A transceiver controller 153 and base band circuit 154 are also included to interface with the RF chip 133 which includes an RF circuit 155 and RF resonators and inductors 156 connected to the antenna 112.

10 The controlling processor 145 captures and decodes location data from tags from the surface via the image sensor 132, monitors the force sensor photodiode 144, controls the LEDs 116, 131 and 143, and handles short-range radio communication via the radio transceiver 153. It is a medium-performance (~40MHz) general-purpose RISC processor.

The processor 145, digital transceiver components (transceiver controller 153 and  
15 baseband circuit 154), image sensor interface 152, flash memory 147 and 512KB DRAM 148 are integrated in a single controller ASIC. Analog RF components (RF circuit 155 and RF resonators and inductors 156) are provided in the separate RF chip.

The image sensor is a 215x215 pixel CCD (such a sensor is produced by Matsushita Electronic Corporation, and is described in a paper by Itakura, K T Nobusada, N  
20 Okusanya, R Nagayoshi, and M Ozaki, "A 1mm 50k-Pixel IT CCD Image Sensor for Miniature Camera System", IEEE Transactions on Electronic Devices, Volt 47, number 1, January 2000, which is incorporated herein by reference) with an IR filter. Other types of image sensors may be used, such as CMOS type image sensors. The minimum pixel count can be more or less, depending on the resolution required.

25 The controller ASIC 134 enters a quiescent state after a period of inactivity when the pen 101 is not in contact with a surface. It incorporates a dedicated circuit 150 which monitors the force sensor photodiode 144 and wakes up the controller 134 via the power manager 151 on a pen-down event.

The radio transceiver communicates in the unlicensed 900MHz band normally used by  
30 cordless telephones, or alternatively in the unlicensed 2.4GHz industrial, scientific and

medical (ISM) band, and uses frequency hopping and collision detection to provide interference-free communication.

In an alternative embodiment, the pen incorporates an Infrared Data Association (IrDA) interface for short-range communication with a base station or netpage printer. The pen  
5 may be connected by wires to a printer, but this does limit its usefulness.

In a further embodiment, the pen 101 includes a pair of orthogonal accelerometers mounted in the normal plane of the pen 101 axis. The accelerometers 190 are shown in Figures 9 and 10 in ghost outline.

The provision of the accelerometers enables this embodiment of the pen 101 to sense  
10 motion without reference to surface location tags, allowing the location tags to be sampled at a lower rate. Each location tag ID can then identify an object of interest rather than a position on the surface. For example, if the object is a user interface input element (e.g. a command button), then the tag ID of each location tag within the area of the input element can directly identify the input element.

15 The acceleration measured by the accelerometers in each of the x and y directions is integrated with respect to time to produce an instantaneous velocity and position.

Since the starting position of the stroke is not known, only relative positions within a stroke are calculated. Although position integration accumulates errors in the sensed acceleration, accelerometers typically have high resolution, and the time duration of a  
20 stroke, over which errors accumulate, is short.

## **7. NETPAGE PRINTER DESCRIPTION**

### **7.1 PRINTER MECHANICS**

The vertically-mounted netpage wallprinter 601 is shown fully assembled in Figures 11 and 12. As best shown in Figures 12, 12a and 68, it prints netpages on A4 sized media  
25 using duplexed 8½" Memjet™ print engines 602 and 603. It uses a straight paper path with the paper 604 passing through duplexed print engines 602 and 603 which print both sides of a sheet simultaneously, in full color and with full bleed. A multi-DSP raster image processor (RIP) rasterizes pages to internal memory, and a pair of custom print engine controllers expand, dither and print page images to the duplexed printheads in

real time.

An integral binding assembly 605 applies a strip of glue along one edge of each printed sheet, allowing it to adhere to the previous sheet when pressed against it. This creates a final bound document 618 which can range in thickness from one sheet to several hundred sheets. The binding assembly will be considered in close detail below with particular reference to Figures 62, 63 and 64.

Referring to Figures 11, 12, 12a, 13 and 53 to 58, the wallprinter 601 consists of a main chassis 606, which accommodates all major components and assemblies. As best shown in Figure 58, it has a pivoting media tray 607 on the front upper portion, which is covered by a front molding 608 and handle molding 609. The front molding 608, handle molding 609 and lower front molding 610 can vary in color, texture and finish to make the product more appealing to consumers. They simply clip onto the front of the wallprinter 601.

Figures 59 and 60 show the wallprinter electrical system in isolation. A flexible printed circuit board (flex PCB) 611 runs from the media tray 607 to the main PCB 612. It includes four different color LEDs 613, 614, 615 and 616 and a push button 617. The LEDs show through the front molding and indicate "on" 613, "ink out" 614, "paper out" 615, and "error" 616. The push button 617 elicits printed "help" in the form of usage instructions, printer and consumable status information, and a directory of resources on the netpage network.

Printed, bound documents 618 exit through the base of the wallprinter 601 into a clear, plastic, removable collection tray 619. This is discussed in greater detail below with specific reference to Figure 64.

The wallprinter 601 is powered by an internal 110V/220V power supply 620 and has a metal mounting plate 621 that is secured to a wall or stable vertical surface by four screws. Plunged keyhole slot details 622 in the metal plate 621 allow for four spigots mounted on the rear of the printer to hook onto the plate. The wallprinter 601 is prevented from being lifted off by a screw that locates the chassis molding 606 to the plate 621 at one position behind the media tray 607.

Referring to Figures 53, 65 and 66, the side of the wallprinter 601 includes a module bay

624 which accommodates a network interface module 625 which allows the printer to be connected to the netpage network and to a local computer or network. The interface module 625 can be selected and installed in the factory or in the field to provide the interfaces required by the user. The modules may have common connector options, such as: IEEE 1394 (Firewire) connection, standard Centronics printer port connection or a combined USB2 649 and Ethernet 650 connection. This allows the consumer to connect the wallprinter 601 to a computer or use it as a network printer. Other types of connections may be used. Figure 66 shows the exploded assembly of the module 625. The interface module PCB 651, (with gold contact edge strips) plugs directly into the main wallprinter PCB 612 via an edge connector 654. The different connector configurations are accommodated in the module design by use of a tool insert 652. Finger recesses 653 on either side of the module 625 allow for easy manual insertion or removal.

Turning to Figure 68, the main PCB 612 is attached to the rear of the chassis 606. The board 612 interfaces through the chassis molding 606 to the interface module 625. The PCB 612 also carries the necessary peripheral electronics to the Memjet™ printheads 705. This includes a main CPU with volatile memory (presently two 32MB DRAMs are used), flash memory, IEEE 1394 interface chip, motor controllers (presently six), various sensor connectors, interface module PCB edge connector, power management, internal/external data connectors and a QA chip.

Figure 58 shows the front hatch access to the paper 604 and the ink cartridge 627. Referring to Figure 67, paper 604 is placed into a hinged top tray 607 and pressed down onto a sprung platen 666. The tray 607 is mounted to the chassis 606 via hinges 700. Each hinge has a base, a hinge lever and a hinge side. Pivots on the base and paper/media tray 607 engage the lever and side such that the paper/media tray 607 rotates in a manner that avoids kinking the supply hoses 646. Other paper tray designs may be used.

The paper 604 is positioned under edge guides 667 before being closed and is automatically registered to one side of the tray 607 by action of a metal spring part 668. An ink cartridge 627 connects into a pivoting ink connector molding 628 via a series of self-sealing connectors 629. The connectors 629 transmit ink, air and glue to their

separate locations. The ink connector molding 628 contains a sensor, which detects a QA chip on the ink cartridge and verifies identification prior to printing. When the front hatch is sensed closed, a release mechanism allows the sprung platen 666 to push the paper 604 against a motorized media pick-up roller assembly 626.

- 5 Figure 54, shows the complete assembly of the replaceable ink cartridge 627. It has bladders or chambers for storing fixative 644, adhesive 630, and cyan 631, magenta 632, yellow 633, black 634 and infrared 635 inks. The cartridge 627 also contains a micro air filter 636 in a base molding 637. As shown in Figure 13, the micro air filter 636 interfaces with an air pump 638 inside the printer via a hose 639. This provides filtered  
10 air to the printheads 705 to prevent ingress of micro particles into the Memjet™ printheads 705 which may clog the nozzles. By incorporating the air filter 636 within the cartridge 627, the operational life of the filter is effectively linked to the life of the cartridge. This ensures that the filter is replaced together with the cartridge rather than relying on the user to clean or replace the filter at the required intervals. Furthermore, the  
15 adhesive and infrared ink are replenished together with the visible inks and air filter thereby reducing how frequently the printer operation is interrupted because of the depletion of a consumable material.

The cartridge 627 has a thin wall casing 640. The ink bladders 631 to 635 and fixative bladder 644 are suspended within the casing by a pin 645 which hooks the cartridge  
20 together. The single glue bladder 630 is accommodated in the base molding 637. This is a fully recyclable product with a capacity for printing and gluing 3000 pages (1500 sheets).

Referring to Figures 12, 12a, 59, 60 and 68, the motorized media pick-up roller assembly 626 pushes the top sheet directly from the media tray 607 past a paper sensor (not  
25 shown) on the first print engine 602 into the duplexed Memjet™ printhead assembly.

Two Memjet™ print engines 602 and 603 are mounted in an opposing in-line sequential configuration along the straight paper path. The paper 604 is drawn into the first print engine 602 by integral, powered pick-up rollers 626. The position and size of the paper 604 is sensed and full bleed printing commences.

- 30 Fixative is printed simultaneously to aid drying in the shortest possible time.

As best shown in Figure 12a, the Memjet™ print engines 602 and 603 include a rotary capping, blotting and platen device 669. The capping device seals the Memjet™ printheads 705 when not in use. It uncaps and rotates to produce an integral blotter, which is used for absorbing ink fired from the printheads 705 during routine printer startup maintenance. It simultaneously moves an internal capping device inside the Memjet™ printhead 705 that allows air to flow into the protective nozzle shield area. The third rotation of the device moves a platen surface into place, which supports one side of the sheet 604 during printing.

The paper exits the first Memjet™ print engine 602 through a set of powered exit spike wheels (aligned along the straight paper path), which acts against a rubberized roller. These spike wheels contact the 'wet' printed surface and continue to feed the sheet 604 into the second Memjet™ print engine 603.

This second print engine 603 is mounted the opposite way up to the first in order to print the underside of the sheet 604.

As shown in Figures 12, 12a, 13, 62 and 63, the paper 604 passes from the duplexed print engines 602 and 603, into the binder assembly 605. The printed page passes between a powered spike wheel axle 670 with a fibrous support roller and another movable axle with spike wheels and a momentary action glue wheel 673. The movable axle/glue assembly 673 is mounted to a metal support bracket and it is transported forward to interface with the powered axle 670 by action of a camshaft 642. A separate motor powers 675 this camshaft. Both motors 676 are controlled by the Memjet™ printheads.

The glue wheel assembly 673 consists of a partially hollow axle 679 with a rotating coupling 680 for the glue supply hose 641 from the ink cartridge 627. This axle 679 connects to a glue wheel 681, which absorbs adhesive by capillary action through radial holes. A molded housing surrounds the glue wheel 681, with an opening at the front. Pivoting side moldings 683 and sprung outer doors 684 are attached to the metal support bracket and hinge out sideways when the rest of the assembly 673 is thrust forward. This action exposes the glue wheel 681 through the front of the molded housing. Tension springs 685 close the assembly and effectively cap the glue wheel 681 during periods of inactivity.

As the sheet 604 passes into the glue wheel assembly 673, adhesive is applied to one vertical edge on the front side (apart from the first sheet of a document) as it is transported down into the binding assembly 605. It will be appreciated that this arrangement applies adhesive to each page during printing so that the paper movement  
5 through the printer is not interrupted or stopped at a separate gluing station. This increases the printer speed, however, it requires that the pages move through the printer in "portrait" configuration (that is, in a direction parallel to the long edges). This in turn requires the paper tray, binding station and collection station to be in portrait configuration. This may make the overall length of the printer too great to conveniently  
10 fit into areas having limited space. In these situations, the media tray, binding station and collection station can be arranged in "landscape" orientation (short sides parallel to paper movement) to shorten the length of the printer. However, the gluing assembly must still be able to apply glue along the long side of the pages. In this version of wallprinter (not shown), the adhesive is applied to the longitudinal edge of each page with a  
15 reciprocating glue strip.

The "portrait" binder assembly 605 is best shown in Figure 62. It has a metal support chassis 686, a sprung molded binding platen 687 that runs on four traverser rods, a molded angled platen 689 which supports the document 618 after the sheet 604 has been moved across, and an exit hatch 690 with support bracket 691. The printed page 604 is  
20 fed in until it rests on the exit hatch 690. The binding platen 687 is propelled forward at high speed via a looped system of wheels 692 and a sprung steel cable 693 that attaches to a powered cable winder shaft 694. As the cable winder shaft 694 is rotated, the cable loop 693 shortens and transports the binding platen 687 forward. This powered shaft 694 has a slip clutch mechanism and provides the necessary speed to push the sheet 604  
25 forward onto the rear of a previous sheet, glue/bind it then return under the action of return springs 699 to the home position to accept the next printed sheet. A single operating cycle of the reciprocating platen takes less than 2 seconds.

The binding assembly 605 binds pages one by one into a bound document, thereby producing bound documents without significantly adding to the time taken to print the  
30 separate pages of the document. Furthermore it applies the adhesive directly prior to pressing it against the previous page. This is more effective than applying adhesive to the

rear of each page and sequentially pressing each page to the subsequent page because any interruption in the printing process such as replenishing the paper supply may allow the adhesive applied to the last adhered page to deteriorate and become less effective.

- 5 The cable 693 is sprung to allow for positive pressure to be applied to the previous sheet to aid binding. Furthermore, the angled platen 689 is shallower at the top than at the base in order to support the document 618 in an over axis configuration.

A sensor (not shown) operatively connected to the control of the stepper motor, may be used to determine the position of the last page bound to the document to allow the platen to accurately adhere the next page to it.

- 10 A paper tapper 643 knocks the sheet 604 to one side of the binder 605 as it is transported across to the angled platen 689. The main PCB 612 controls motors 695, 696 and 697 for the cable winder shaft 694, the tapper 643 and the exit hatch 690 respectively.

- When a document 618 is bound and finished, the powered exit hatch 690 opens. A tamper sensor (not shown) is provided to detect document jams or other interferences acting to prevent the exit hatch 690 from closing. The tapper 643 also tap aligns the printed document 618 during ejection out of the binder 605 into the collection tray 619. Plastic foils 698 on the lower front molding 610 work together with the hatch 690 to direct the finished document 618 to the back of the collection tray 619 and feed any further documents into the tray without hitting existing ones. A plurality the flexible foils may be provided, each having different lengths to accommodate documents having different page sizes. The collection tray 619 is molded in clear plastic and pulls out of its socket under a certain loading. Access for removing documents is provided on three sides.
- 15  
20

## 7.2 MEMJET-BASED PRINTING

- 25 A Memjet™ printhead produces 1600 dpi bi-level CMYK. On low-diffusion paper, each ejected drop forms an almost perfectly circular 22.5µm diameter dot. Dots are easily produced in isolation, allowing dispersed-dot dithering to be exploited to its fullest.

A page layout may contain a mixture of images, graphics and text. Continuous-tone (contone) images and graphics are reproduced using a stochastic dispersed-dot dither.

Unlike a clustered-dot (or amplitude-modulated) dither, a dispersed-dot (or frequency-modulated) dither reproduces high spatial frequencies (i.e. image detail) almost to the limits of the dot resolution, while simultaneously reproducing lower spatial frequencies to their full color depth, when spatially integrated by the eye. A stochastic dither matrix is carefully designed to be free of objectionable low-frequency patterns when tiled across the image. As such its size typically exceeds the minimum size required to support a particular number of intensity levels (e.g.  $16 \times 16 \times 8$  bits for 257 intensity levels).

Human contrast sensitivity peaks at a spatial frequency of about 3 cycles per degree of visual field and then falls off logarithmically, decreasing by a factor of 100 beyond about 40 cycles per degree and becoming immeasurable beyond 60 cycles per degree. At a normal viewing distance of 12 inches (about 300mm), this translates roughly to 200-300 cycles per inch (cpi) on the printed page, or 400-600 samples per inch according to Nyquist's theorem.

In practice, contone resolution above about 300 ppi is of limited utility outside special applications such as medical imaging. Offset printing of magazines, for example, uses contone resolutions in the range 150 to 300 ppi. Higher resolutions contribute slightly to color error through the dither.

Black text and graphics are reproduced directly using bi-level black dots, and are therefore not anti-aliased (i.e. low-pass filtered) before being printed. Text is therefore super-sampled beyond the perceptual limits discussed above, to produce smoother edges when spatially integrated by the eye. Text resolution up to about 1200 dpi continues to contribute to perceived text sharpness (assuming low-diffusion paper, of course).

The netpage printer uses a contone resolution of 267 ppi (i.e.  $1600 \text{ dpi} / 6$ ), and a black text and graphics resolution of 800 dpi.

### 7.3 DOCUMENT DATA FLOW

Because of the pagewidth nature of the Memjet™ printhead, each page must be printed at a constant speed to avoid creating visible artifacts. This means that the printing speed can't be varied to match the input data rate. Document rasterization and document printing are therefore decoupled to ensure the printhead has a constant supply of data. A page is never printed until it is fully rasterized. This is achieved by storing a compressed

version of each rasterized page image in memory.

This decoupling also allows the raster image processor (RIP) to run ahead of the printer when rasterizing simple pages, buying time to rasterize more complex pages.

Because contone color images are reproduced by stochastic dithering, but black text and  
5 line graphics are reproduced directly using dots, the compressed page image format contains a separate foreground bi-level black layer and background contone color layer. The black layer is composited over the contone layer after the contone layer is dithered.

Netpage tags are rendered to a separate layer and are ultimately printed using infrared-absorptive ink.

- 10 At 267 ppi, a Letter size page of contone CMYK data has a size of 25MB. Using lossy contone compression algorithms such as JPEG (ISO/IEC 19018-1:1994, Information technology - Digital compression and coding of continuous-tone still images: Requirements and guidelines, 1994, the contents of which are herein incorporated by cross-reference), contone images compress with a ratio up to 10:1 without noticeable  
15 loss of quality, giving a compressed page size of 2.5MB. Lossless compression algorithms may be used but these do not usually result in as high compression ratios compared to lossy compression algorithms.

- At 800 dpi, a Letter size page of bi-level data has a size of 7MB. Coherent data such as text compresses very well. Using lossless bi-level compression algorithms such as Group  
20 4 Facsimile (ANSI/EIA 538-1988, Facsimile Coding Schemes and Coding Control Functions for Group 4 Facsimile Equipment, August 1988, the contents of which are herein incorporated by cross-reference), ten-point text compresses with a ratio of about 10:1, giving a compressed page size of 0.8MB.

- Once dithered, a Letter size page of CMYK contone image data consists of 114MB of bi-  
25 level data. Using lossless bi-level compression algorithms on this data is pointless precisely because the optimal dither is stochastic - i.e. since it introduces hard-to-compress disorder.

- The two-layer compressed page image format therefore exploits the relative strengths of  
30 lossy JPEG contone image compression and lossless bi-level text compression. The format is compact enough to be storage-efficient, and simple enough to allow

straightforward real-time expansion during printing.

Since text and images normally don't overlap, the normal worst-case page image size is 2.5MB (i.e. image only), while the normal best-case page image size is 0.8MB (i.e. text only). The absolute worst-case page image size is 3.3MB (i.e. text over image).

- 5 Assuming a quarter of an average page contains images, the average page image size is 1.2MB.

#### 7.4 PRINTER CONTROLLER ARCHITECTURE

- The netpage printer controller consists of a controlling processor 750, a factory-installed or field-installed network interface module 625, a radio transceiver (transceiver  
10 controller 753, baseband circuit 754, RF circuit 755, and RF resonators and inductors 756), dual raster image processor (RIP) DSPs 757, duplexed print engine controllers 760a and 760b, flash memory 658, and DRAM 657 (presently 64MB), as illustrated in Figure 63.

- The controlling processor handles communication with the network 19 and with local  
15 wireless netpage pens 101, senses the help button 617, controls the user interface LEDs 613-616, and feeds and synchronizes the RIP DSPs 757 and print engine controllers 760. It consists of a medium-performance general-purpose microprocessor. The controlling processor 750 communicates with the print engine controllers 760 via a high-speed serial bus 659.

- 20 The RIP DSPs rasterize and compress page descriptions to the netpage printer's compressed page format. Each print engine controller expands, dithers and prints page images to its associated Memjet™ printhead 350 in real time (i.e. at over 30 pages per minute). The duplexed print engine controllers print both sides of a sheet simultaneously.

- The master print engine controller 760a controls the paper transport and monitors ink  
25 usage in conjunction with the master QA chip 665 and the ink cartridge QA chip 761.

The printer controller's flash memory 658 holds the software for both the processor 750 and the DSPs 757, as well as configuration data. This is copied to main memory 657 at boot time.

The processor 750, DSPs 757, and digital transceiver components (transceiver controller

753 and baseband circuit 754) are integrated in a single controller ASIC 656. Analog RF components (RF circuit 755 and RF resonators and inductors 756) are provided in a separate RF chip 762. The network interface module 625 is separate, since netpage printers allow the network connection to be factory-selected or field-selected. Flash memory 658 and the 2×256Mbit (64MB) DRAM 657 is also off-chip. The print engine controllers 760 are provided in separate ASICs.

A variety of network interface modules 625 are provided, each providing a netpage network interface 751 and optionally a local computer or network interface 752. Netpage network Internet interfaces include POTS modems, Hybrid Fiber-Coax (HFC) cable modems, ISDN modems, DSL modems, satellite transceivers, current and next-generation cellular telephone transceivers, and wireless local loop (WLL) transceivers. Local interfaces include IEEE 1284 (parallel port), 10Base-T and 100Base-T Ethernet, USB and USB 2.0, IEEE 1394 (Firewire), and various emerging home networking interfaces. If an Internet connection is available on the local network, then the local network interface can be used as the netpage network interface.

The radio transceiver 753 communicates in the unlicensed 900MHz band normally used by cordless telephones, or alternatively in the unlicensed 2.4GHz industrial, scientific and medical (ISM) band, and uses frequency hopping and collision detection to provide interference-free communication.

The printer controller optionally incorporates an Infrared Data Association (IrDA) interface for receiving data “squirted” from devices such as netpage cameras. In an alternative embodiment, the printer uses the IrDA interface for short-range communication with suitably configured netpage pens.

#### 7.4.1 RASTERIZATION AND PRINTING

As shown in Figure 52, once the main processor 750 has received and verified (at 550) the document’s page layouts and page objects into memory 657 (at 551), it runs the appropriate RIP software on the DSPs 757.

The DSPs 757 rasterize (at 552) each page description and compress (at 553) the rasterized page image. The main processor stores each compressed page image in memory 657 (at 554). The simplest way to load-balance multiple DSPs is to let each

DSP rasterize a separate page. The DSPs can always be kept busy since an arbitrary number of rasterized pages can, in general, be stored in memory. This strategy only leads to potentially poor DSP utilization when rasterizing short documents.

Watermark regions in the page description are rasterized to a contone-resolution bi-level  
5 bitmap which is losslessly compressed to negligible size and which forms part of the compressed page image.

The infrared (IR) layer of the printed page contains coded netpage tags at a density of about six per inch. Each tag encodes the page ID, tag ID, and control bits, and the data content of each tag is generated during rasterization and stored in the compressed page  
10 image.

The main processor 750 passes back-to-back page images to the duplexed print engine controllers 760. Each print engine controller 760 stores the compressed page image in its local memory 769, and starts the page expansion and printing pipeline. Page expansion and printing is pipelined because it is impractical to store an entire 114MB bi-level  
15 CMYK+IR page image in memory.

The print engine controller expands the compressed page image (at 555), dithers the expanded contone color data to bi-level dots (at 556), composites the expanded bi-level black layer over the dithered contone layer (at 557), renders the expanded netpage tag data (at 558), and finally prints the fully-rendered page (at 559) to produce a printed  
20 netpage 1.

#### 7.4.2 PRINT ENGINE CONTROLLER

The page expansion and printing pipeline of the print engine controller 760 consists of a high speed IEEE 1394 serial interface 659, a standard JPEG decoder 763, a standard Group 4 Fax decoder 764, a custom halftoner/compositor unit 765, a custom tag encoder  
25 766, a line loader/formatter unit 767, and a custom interface 768 to the Memjet™ printhead 350.

The print engine controller 360 operates in a double buffered manner. While one page is loaded into DRAM 769 via the high speed serial interface 659, the previously loaded page is read from DRAM 769 and passed through the print engine controller pipeline.

Once the page has finished printing, the page just loaded is printed while another page is loaded.

The first stage of the pipeline expands (at 763) the JPEG-compressed contone CMYK layer, expands (at 764) the Group 4 Fax-compressed bi-level black layer, and renders (at 766) the bi-level netpage tag layer according to the tag format defined in section 1.2, all in parallel. The second stage dithers (at 765) the contone CMYK layer and composites (at 765) the bi-level black layer over the resulting bi-level CMYK layer. The resultant bi-level CMYK+IR dot data is buffered and formatted (at 767) for printing on the Memjet™ printhead 350 via a set of line buffers. Most of these line buffers are stored in the off-chip DRAM. The final stage prints the six channels of bi-level dot data (including fixative) to the Memjet™ printhead 350 via the printhead interface 768.

When several print engine controllers 760 are used in unison, such as in a duplexed configuration, they are synchronized via a shared line sync signal 770. Only one print engine 760, selected via the external master/slave pin 771, generates the line sync signal 770 onto the shared line.

The print engine controller 760 contains a low-speed processor 772 for synchronizing the page expansion and rendering pipeline, configuring the printhead 350 via a low-speed serial bus 773, and controlling the stepper motors 675, 676.

In the 8½" versions of the netpage printer, the two print engines each prints 30 Letter pages per minute along the long dimension of the page (11"), giving a line rate of 8.8 kHz at 1600 dpi. In the 12" versions of the netpage printer, the two print engines each prints 45 Letter pages per minute along the short dimension of the page (8½"), giving a line rate of 10.2 kHz. These line rates are well within the operating frequency of the Memjet™ printhead, which in the current design exceeds 30 kHz.

## 25 CONCLUSION

The present invention has been described with reference to a preferred embodiment and number of specific alternative embodiments. However, it will be appreciated by those skilled in the relevant fields that a number of other embodiments, differing from those specifically described, will also fall within the spirit and scope of the present invention. Accordingly, it will be understood that the invention is not intended to be limited to the

[illegible]

## CLAIMS

1. A printer for printing a second interface onto a second surface, in response to first indicating data received from a sensing device, the first indicating data being sensed by the sensing device from first coded data, a first interface disposed on a first surface including the first coded data, the printer including:
- 5 (a) an input module configured to:
- (i) receive, from the sensing device, the first indicating data, the first indicating data being at least partially indicative of response data;
- 10 (ii) generate second indicating data based on the first indicating data, the second indicating data being at least partially indicative of the response data;
- (iii) send the second indicating data to a computer system; and
- (b) a printing module, including a printing mechanism, configured to:
- 15 (i) receive the response data from the computer system;
- (ii) generate the second interface based at least partially on the response data; and
- (iii) print the second interface onto the second surface using the printing mechanism.
- 20
2. A printer according to claim 1, the second interface including second coded data, wherein the printing module includes a coded data generator configured to generate the second coded data based on at least part of the response data.
- 25 3. A printer according to claim 2, the response data including second region identity data indicative of at least one identity, the identity being associated with a region of the second interface, the coded data generator being configured to generate the second coded

data based on the second region identity data, the second coded data being indicative of the identity.

4. A printer according to any one of the preceding claims, wherein the second  
5 interface includes visible information in addition to the second coded data, the visible information being based at least partially on the response data.

5. A printer according to claim 3, wherein the second coded data is also indicative of at least one reference point of the region.

10

6. A printer according to claim 5, wherein the at least one reference point is determined on the basis of a coded data layout.

7. A printer according to claim 6, wherein the printing module is configured to  
15 receive the coded data layout from the computer system.

8. A printer according to claim 6, further including storage means for storing a plurality of the coded data layouts, the printing module being configured to:

receive, from the computer system, layout selection information indicative of one of the  
20 coded data layouts; and

use the layout selection information to select one of the stored coded layouts for use in determining the at least one reference point.

9. A printer according to claim 1, wherein the first indicating data includes location  
25 data sensed by the sensing device from the first coded data.

10. A printer according to claim 1, wherein the first indicating data includes first

region identity data sensed by the sensing device from the first coded data, the first region identity data being indicative of an identity associated with a region of the first interface, the region being at least partially indicative of the response data.

5 11. A printer according to claim 10, wherein the first indicating data includes location data sensed by the sensing device from the first coded data, the location data being indicative of a location within the region, the location within the region being at least partially indicative of the response data.

10 12. A printer according to any one of claims 1 to 3 or 5 to 11, wherein the second coded data includes at least one tag, each tag being indicative of the identity of the region.

13. A printer according to claim 12, wherein the second coded data includes a  
15 plurality of the tags, the coded data generator being configured to ascertain a position of each tag prior to printing, the respective positions being determined on the basis of a coded data layout.

14. A printer according to claim 13, wherein the coded data generator is configured  
20 to receive the coded data layout from the computer device prior to printing the second coded data.

15. A printer according to claim 7, further including storage means for storing a plurality of the coded data layouts, the coded data generator being configured to:  
25 receive, from the computer device, layout selection information indicative of one of the coded data layouts; and  
generate the second coded data based on the layout selection information.

16. A printer according to claim 13, wherein each of the tags includes:  
first identity data defining a relative position of that tag; and  
second identity data identifying the surface.
- 5 17. A printer according to any one of claims 1 to 3 or 5 to 11, the printer being configured to print the second interface onto the second surface on demand.
18. A printer according to any one of claims 1 to 3 or 5 to 11, wherein the second interface is printed over a plurality of the pages.
- 10 19. A printer according to claim 1, wherein the first and/or second surfaces are defined by a substrate.
20. A printer according to claim 19, wherein the substrate is laminar.
- 15 21. A printer according to claim 12, wherein the tags are disposed at predetermined positions on the second surface.
22. A printer according to claim 21, wherein the tags are disposed on the surface  
20 within a tessellated pattern comprising a plurality of tiles, each of the tiles containing a plurality of the tags.
23. A printer according to claim 22, wherein the tiles interlock with each other to substantially cover the surface.
- 25 24. A printer according to claim 23, wherein the tiles are all of a similar shape.

25. A printer according to claim 24, wherein the tiles are triangular, square, rectangular or hexagonal.

5 26. A printer according to claim 22, wherein the tags are disposed stochastically within each of the tiles.

27. A printer according to claim 12, wherein each of the tags includes at least one common feature in addition to the second identity data.

10

28. A printer according to claim 27, wherein at least one common feature is configured to assist finding and/or recognition of the tags by associated tag reading apparatus.

15 29. A printer according to claim 27, wherein the at least one common feature is represented in a format incorporating redundancy of information.

30. A printer according to claim 29, wherein the at least one common feature is rotationally symmetric so as to be rotationally invariant.

20

31. A printer according to claim 29, wherein the at least one common feature is ring-shaped.

25 32. A printer according to claim 12, wherein each of the tags includes at least one orientation feature for enabling a rotational orientation of the tag to be ascertained by associated tag reading apparatus.

33. A printer according to claim 32, wherein the at least one orientation feature is represented in a format incorporating redundancy of information.

34. A printer according to claim 33, wherein the at least one orientation feature is  
5 rotationally asymmetric.

35. A printer according to claim 33, wherein the at least one orientation feature is skewed along its major axis.

10 36. A printer according to claim 12, wherein each of the tags includes at least one perspective feature for enabling a perspective distortion of the tag to be ascertained by associated tag reading apparatus.

37. A printer according to claim 36, wherein the at least one perspective feature  
15 includes at least four sub-features which are not coincident.

38. A printer according to claim 12, wherein each tag includes a plurality of tag elements, the first and second identity data each being defined by a plurality of the elements.

20

39. A printer according to claim 38, wherein the tag elements are disposed in one or more arcuate bands around a central region of each tag.

40. A printer according to claim 39, wherein there are a plurality of the arcuate bands  
25 disposed concentrically with respect to each other.

41. A printer according to claim 40, wherein each element takes the form of a dot

having a plurality of possible values.

42. A printer according to claim 41, wherein the number of possible values is two.

5 43. A printer according to claim 41, wherein when representing one of the possible values, the tag elements absorb, reflect or fluoresce electromagnetic radiation of a predetermined wavelength or range of wavelengths to a predetermined greater or lesser extent than the second surface.

10 44. A printer according to claim 41, wherein the possible values of the tag elements are defined by different relative absorption, reflection or fluorescence of electromagnetic radiation of a predetermined wavelength or range of wavelengths.

15 45. A printer according to claim 41, wherein the tags are not substantially visible to an average unaided human eye under daylight or ambient lighting conditions.

46. A printer according to claim 41, wherein the tags are slightly visible to an average unaided human eye under daylight or ambient lighting conditions.

20 47. A printer according to claim 38, wherein the tags are visible to an average unaided human eye under daylight or ambient lighting conditions.

48. A printer according to claim 13, wherein the first identity data is represented in a format incorporating redundancy of information.

25

49. A printer according to claim 13, wherein the second identity data is represented in a format incorporating redundancy of information.

50. A printer according to claim 49, wherein the printer is an ink printer.
51. A printer according to claim 50, wherein the tags are printed using ink that is  
5 absorbent or reflective in the ultraviolet spectrum or the infrared spectrum.
52. A printer according to claim 51, wherein the printer includes a separate ink channel for printing the tags.
- 10 53. A printer according to claim 50, wherein the printer is configured to print the second coded data and additional information substantially simultaneously onto the second surface.
54. A printer according to claim 53, wherein the additional information is printed  
15 onto the second surface using colored or monochrome inks.
55. A printer according to claim 54, wherein the additional information is printed onto the second surface using one of the following combinations of colored inks:
- CMY;
- 20 CMYK;
- CMYRGB; and
- spot color.
56. A printer according to any one of claims 9 to 11, wherein at least a plurality of  
25 the tags are disposed stochastically upon the second surface.

57. A printer according to any one of claims 9 to 11, wherein the tags are disposed in a regular array on the second surface, in accordance with the coded layout data.

58. A printer according to claim 57, wherein the array is triangular.

5

59. A printer according to claim 57, wherein the array is rectangular.

60. A printer according to claim 57, wherein the tags are tiled over the second surface.

10

63. A printer according to claim 62, further including a binding mechanism for binding the pages into a bound document.

15

64. A printer according to claim 53, wherein the second surface is defined by a face of a page, the printer further including dual printing mechanisms for printing opposite faces of the page simultaneously.

65. A printer according to any one of claims 1 to 3 or 5 to 11, wherein the printing mechanism includes an inkjet printhead for printing ink onto the second surface.

20

66. A printer according to claim 65, wherein the printhead is a drop on demand inkjet printhead.

67. A printer according to claim 66, wherein the printhead is a pagewidth printhead.

25

68. A printer according to claim 67, wherein the printhead is configured to deliver a plurality of ink colors onto the second surface with one printing pass.

69. A printer according to claim 67, wherein the printhead includes electro-thermal bend actuators to eject the ink onto the surface.

5 70. A printer according to any one of claims 69, wherein the printer includes two sets of printheads, configured to print opposite surfaces of a page substantially simultaneously.

10 71. A printer according to claim 69, including a forced filtered air delivery mechanism for keeping nozzles of the printhead relatively free of paper dust.

72. A printer according to claim 69, wherein the printhead includes moving nozzle chambers.

15 73. A printer according to claim 72, wherein the printer includes two sets of printheads, configured to print opposite surfaces of a page substantially simultaneously.

74. A printer according to claim 1, wherein the first indicating data includes user identity data, the user identity data being indicative of user data.

20

75. A printer according to claim 74, wherein the user identity data is supplied from storage means associated with the sensing device.

25 76. A printer according to any one of claims 1 to 3, 5 to 11, 15 or 16, wherein the first interface surface is on the printer.

77. A system including:

a printer according to any one of claims 1 to 3, 5 to 11, 15 or 16; and

a sensing device for sensing the first indicating data and transmitting it to the printer.

78. A system according to claim 77, wherein the sensing device includes a radio  
5 transmitter for transmitting the indicating data to the printer, and the printer includes a  
radio receiver for receiving the indicating data.

79. A system according to claim 77, wherein the sensing device includes an optical  
sensor for sensing the first coded data.

10

79. A system including:

a printer according to any one of claims 1 to 3, 5 to 11, 15 or 16; and

a first interface surface disposed on a first surface, the first interface surface including  
first coded data to be sensed by a sensing device, thereby to generate first indicating data  
15 for transmission from the sensing device to the printer.

80. An interface surface produced by a printer according to any one of claims 1 to 3,  
5 to 11, 15 or 16.

20

## ABSTRACT

A printer for printing a second interface onto a second surface, in response to first indicating data received from a sensing device in the form of a stylus. The first indicating data is sensed by the stylus from first coded data. A first interface is disposed on a first surface, and includes the first coded data. The printer includes an input module and a printing module. The input module is configured to receive the first indicating data from the stylus, the first indicating data being at least partially indicative of response data. The input module generates second indicating data based on the first indicating data, the second indicating data being at least partially indicative of the response data. The second indicating data is sent to a computer system. The printing module includes a printing mechanism configured to receive the response data from the computer system. The second interface is based at least partially on the response data. The printing module then prints the second interface onto the second surface using the printing mechanism.
